Clinical Trials: NCCN believes that the best management for any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

To find clinical trials online at NCCN Member Institutions, [click here](nccn.org/clinical_trials/clinicians.aspx).

NCCN Categories of Evidence and Consensus: All recommendations are category 2A unless otherwise indicated.

See [NCCN Categories of Evidence and Consensus](nccn.org/clinical_trials/clinicians.aspx).

NCCN Non-Small Cell Lung Cancer Panel Members
Summary of Guidelines Updates

Lung Cancer Prevention and Screening (PREV-1)
Clinical Presentation and Risk Assessment (DIAG-1)
Initial Evaluation and Clinical Stage (NSCL-1)

Evaluation and Treatment:
- Stage I (T1abc-2a, N0), Stage II (T1abc-2ab, N1; T2b, N0).
- Stage IIIB (T3, N0), and Stage IIIA (T3, N1) (NSCL-2)
- Stage IIIB (T3 invasion, N0) and Stage IIIA (T4 extension, N0-1; T3, N1; T4, N0-1) (NSCL-4)
- Stage IIIA (T1-2, N2); Stage IIIB (T3, N2); Separate Pulmonary Nodules (Stage IIIB, IIIA, IV) (NSCL-7)

Multiple Lung Cancers (N0-1) (NSCL-10)
Stage IIIB (T1-2, N3); Stage IIIC (T3, N3) (NSCL-11)
Stage IIIB (T4, N2); Stage IIIC (T4, N3); Stage IVA, M1a: Pleural or Pericardial Effusion (NSCL-12)
Stage IVA, M1b (NSCL-13)

Surveillance After Completion of Definitive Therapy (NSCL-15)
Therapy for Recurrence and Metastasis (NSCL-16)
Systemic Therapy for Advanced or Metastatic Disease (NSCL-17)

Principles of Pathologic Review (NSCL-A)
Principles of Surgical Therapy (NSCL-B)
Principles of Radiation Therapy (NSCL-C)
Chemotherapy Regimens for Neoadjuvant and Adjuvant Therapy (NSCL-D)
Chemotherapy Regimens Used with Radiation Therapy (NSCL-E)
Cancer Survivorship Care (NSCL-F)
Principles of Molecular and Biomarker Analysis (NSCL-G)
Emerging Biomarkers to Identify Patients with for Therapies (NSCL-H)
Targeted Therapy for Advanced or Metastatic Disease (NSCL-I)
Systemic Therapy for Advanced or Metastatic Disease (NSCL-J)

Staging (ST-1)

The NCCN Guidelines® are a statement of evidence and consensus of the authors regarding their views of currently accepted approaches to treatment. Any clinician seeking to apply or consult the NCCN Guidelines is expected to use independent medical judgment in the context of individual clinical circumstances to determine any patient’s care or treatment. The National Comprehensive Cancer Network® (NCCN®) makes no representations or warranties of any kind regarding their content, use or application and disclaims any responsibility for their application or use in any way. Updates in Version 5.2019 of the NCCN Guidelines for Non-Small Cell Lung Cancer from Version 4.2019 include:

NSCL-27
Clarifications made for PD-L1 expression positive (≥1%) treatment options:
• Adenocarcinoma, large cell, NSCLC NOS: (Carboplatin or cisplatin) + pemetrexed + pembrolizumab (category 1 if PD-L1 ≥50%) (category 1 and preferred if PD-L1 1-49%)
• Squamous cell carcinoma: (Carboplatin or cisplatin) + (paclitaxel or albumin-bound paclitaxel) + pembrolizumab (carboplatin combination: [category 1 if PD-L1 ≥50%] [category 1 and preferred if PD-L1 1-49%])

MS-1
• Discussion section updated based on the changes in the algorithm.

Updates in Version 4.2019 of the NCCN Guidelines for Non-Small Cell Lung Cancer from Version 3.2019 include:

NSCL-17
• PD-L1 expression percentage changed from ≥50% to ≥1% (also applies to NSCL-27, NSCL-I 1 of 2)

NSCL-27
• Pembrolizumab monotherapy added for PD-L1 1-49% with a category 2B designation.
• Footnote bbb added: Pembrolizumab monotherapy can be considered in PD-L1 1-49%, in patients with poor PS or other contraindications to combination chemotherapy.

MS-1
• Discussion section updated based on the changes in the algorithm.

Updates in Version 3.2019 of the NCCN Guidelines for Non-Small Cell Lung Cancer from Version 2.2019 include:

NSCL-17
• Footnote jj added: Testing should include the neurotrophic receptor tyrosine kinase (NTRK) gene fusion; if positive, see NSCL-26.

NSCL-26
• New page added to address the treatment of metastatic NSCLC that is positive for the NTRK gene fusion.

NSCL-I 1 of 2
• Larotrectinib added for NTRK gene fusion positive, including reference.

MS-1
• Discussion section updated based on the changes in the algorithm.

Updates in Version 2.2019 of the NCCN Guidelines for Non-Small Cell Lung Cancer from Version 1.2019 include:

NSCL-22
• ALK rearrangement positive metastatic NSCLC: Lorlatinib added as a treatment option after progression on crizotinib and allectinib, brigatinib, or ceritinib.

NSCL-23
• ALK rearrangement positive metastatic NSCLC: Lorlatinib added as a treatment option, after progression on alectinib, brigatinib, or ceritinib

NSCL-24
• ROS1 rearrangement positive metastatic NSCLC: Lorlatinib added as a treatment option, after progression on crizotinib or ceritinib.
Updates in Version 1.2019 of the NCCN Guidelines for Non-Small Cell Lung Cancer from Version 6.2018 include:

**DIAG-2**
- Footnote g modified: "Non-solid (ground-glass), partially solid, or ground-glass nodules may require longer follow-up to exclude indolent adenocarcinoma." (also applies to DIAG-3)

**DIAG-3**
- Solitary pure ground-glass nodules
  - ≥6 mm
    - Follow-up modified: "CT at 6–12 mo to confirm persistence, no growth or change in solid component, then CT every 2 y until 5 y"
- Solitary part-solid nodule(s); sub-categories modified
  - "Persistent and <6 mm"
  - "Persistent and ≥6 mm"
    - Follow-up modified: CT at 3–6 mo to confirm persistence, no growth or change in solid component, then annual CT for 5 y

**DIAG-A 3 of 3**
- Bullet added: "An EBUS-TBNA negative for malignancy in a clinically (PET and/or CT) positive mediastinum should undergo subsequent mediastinoscopy prior to surgical resection." (also added to footnote h on NSCL-2)
- Bullet modified: "TTNA and anterior mediastinotomy (ie, Chamberlain procedure) provide additional access to anterior mediastinal (station 5 and 6) lymph nodes if these are clinically suspicious. If TTNA is not possible due to proximity to aorta, VATS biopsy is also an option."

**NSCL-2**
- Durvalumab changed from a category 2A to a category 1 recommendation. (also applies to NSCL-5, 6, 8, 11, 12, E)
- Footnote k added: "If MRI is not possible, CT of head with contrast." (also applies to NSCL-4, 7, 9, 11, 12, 13, 16)

**NSCL-5**
- Footnote removed: "If full-dose chemotherapy is not given concurrently with RT as initial treatment, give additional 2 cycles of full-dose chemotherapy." (also applies to NSCL-6, NSCL-11, NSCL-12)
- Footnote text moved to Principles of Radiation Therapy: "RT should continue to definitive dose without interruption if patient is not a surgical candidate." (also applies to NSCL-6)

**NSCL-9**
- Footnote o added: "After surgical evaluation, patients likely to receive adjuvant chemotherapy may be treated with induction chemotherapy as an alternative."

**NSCL-13**
- Footnote bb added: "Including selected patients with stage M1c and limited number and volume of metastatic lesions amenable to definitive local therapy. Limited number is undefined but clinical trials have included up to 3 to 5 metastases."

**NSCL-16**
- Clinical presentation modified: "Locoregional recurrence or symptomatic local disease"
- SVC obstruction
  - Treatment options clarified with the addition of "± SVC stent" to concurrent chemoradiation and external-beam RT.
- Severe hemoptysis
  - Treatment options clarified with addition of "Any combination of the following"
Updates in Version 1.2019 of the NCCN Guidelines for Non-Small Cell Lung Cancer from Version 6.2018 include:

**NSCL-17**
- Adenocarcinoma/Large cell/NSCLC not otherwise specified (NOS); Testing
  - PD-L1 testing changed from category 2A to category 1
- Squamous cell carcinoma; Testing
  - *ROS1* and *BRAF* testing clarified with additional wording: "in small biopsy specimens or mixed histology"
  - PD-L1 testing changed from category 2A to category 1
- PD-L1 $\geq 50\%$ positive: "*ROS1, BRAF* negative or unknown removed." (also applies to NSCL-26)
- Footnote gg modified: "If repeat biopsy is not feasible, plasma biopsy testing should be considered."
- Footnote removed: "PD-L1 expression levels $\geq 50\%$ are a positive test result for first-line pembrolizumab therapy."

**NSCL-18**
- First-line therapy for sensitizing EGFR mutation positive metastatic NSCLC
  - Osimertinib listed as preferred.
  - Dacomitinib added as a category 1 treatment option.

**NSCL-19**
- Subsequent Therapy
  - Asymptomatic
    - "Consider local therapy" changed to "Consider definitive local therapy (eg, SABR or surgery) for limited lesions" (also applies to NSCL-20, NSCL-22, and NSCL-23)
    - Continue dacomitinib added as a treatment option.
  - Brain
    - "Consider local therapy" changed to "Consider definitive local therapy (eg, SRS) for limited lesions" (also applies to NSCL-20, NSCL-22, and NSCL-23)
    - Continue dacomitinib added as a treatment option.
  - Isolated lesion
    - "Consider local therapy" changed to "Consider definitive local therapy (eg, SABR or surgery)" (also applies to NSCL-20, NSCL-22, and NSCL-23)
    - Continue dacomitinib added as a treatment option.
- Footnote pp modified: "If tissue biopsy is not feasible, plasma biopsy should be considered. Consider reflex to tissue-based testing, if plasma test is negative for the *T790M* mutation. Plasma-based testing should be considered at progression on EGFR TKIs for the *T790M* mutation. If plasma-based testing is negative, tissue-based testing with rebiopsy material is strongly recommended. Practitioners may want to consider scheduling the biopsy concurrently with plasma testing referral."
- Footnote rr added: In the randomized phase III trial of dacomitinib, patients with brain metastases were not eligible for enrollment. In the setting of brain metastases, consider other options.
- Footnote tt modified: "The data in the second-line setting suggest that immunotherapy PD-1/PD-L1 inhibitor monotherapy is less effective, irrespective of PD-L1 expression, in tumors with an actionable mutation *EGFR*+ or *ALK*+ NSCLC." (also applies to NSCL-20, NSCL-22, NSCL-23)
- Footnote removed: "For rapid radiologic progression or threatened organ function, alternate therapy should be instituted." (also applies to NSCL-22, NSCL-23)
Updates in Version 1.2019 of the NCCN Guidelines for Non-Small Cell Lung Cancer from Version 6.2018 include:

**NSCL-21**
- ALK rearrangement discovered prior to first-line systemic therapy: Brigatinib added as a category 1 treatment option.
- ALK rearrangement discovered during first-line systemic therapy
  - Alectinib noted as preferred.
  - Brigatinib added as a treatment option.

**NSCL-22**
- Symptomatic brain progression: "continue crizotinib" removed.
- Footnote removed: "If considering WBRT, consider switching ALK inhibitor before using WBRT." (also applies to NSCL-23)

**NSCL-23**
- Subsequent therapy: Continue brigatinib added as a treatment option.

**NSCL-24**
- The following categories added: "ROSI rearrangement discovered during first-line systemic therapy" with the recommendation to "Complete planned systemic therapy, including maintenance therapy, or interrupt, followed by crizotinib (preferred) or ceritinib."
- Footnote removed: "The data in the second-line setting suggest that immunotherapy is less effective, irrespective of PD-L1 expression, in tumors with an actionable mutation."

**NSCL-25**
- The following category added: "BRAF V600E mutation discovered during first-line systemic therapy" with the recommendation to "Complete planned systemic therapy, including maintenance therapy, or interrupt, followed by dabrafenib + trametinib."
- Footnote removed: "At this point, there are no published data on the progression-free survival (PFS) of patients treated in the first-line setting."

**NSCL-26**
- PD-L1 category modified with the addition of "and no contraindications to the addition of pembrolizumab or atezolizumab"
- Histology and performance status added as treatment criteria
- Adenocarcinoma/Large cell/NSCLC NOS
  - Pembrolizumab noted as preferred
  - The following regimens added as category 1
    - (Carboplatin or cisplatin) + pemetrexed + pembrolizumab
    - Carboplatin + paclitaxel + bevacizumab + atezolizumab
  - Continuation maintenance
    - Pembrolizumab added as a category 1 recommendation.

- Squamous cell carcinoma
  - Pembrolizumab noted as preferred
  - The following regimens added as category 1
    - Carboplatin + (paclitaxel or albumin-bound paclitaxel) + pembrolizumab
  - The following regimens added as category 2A
    - Cisplatin + (paclitaxel or albumin-bound paclitaxel) + pembrolizumab
Updates in Version 1.2019 of the NCCN Guidelines for Non-Small Cell Lung Cancer from Version 6.2018 include:

**NSC-26**
- Footnote zz added: "Contraindications for treatment with PD-1/PD-L1 inhibitors may include active or previously documented autoimmune disease and/or current use of immunosuppressive agents or presence of an oncogene which would predict lack of benefit. If contraindications, refer to NSCL-27 (adenocarcinoma) or NSCL-28 (squamous cell carcinoma)." (Also applies to NSCL-J 2 of 4, NSCL-J 3 of 4)
- Footnote aaa added: "If pembrolizumab monotherapy given."
- Footnote ddd added: "If patient has not received platinum-doublet chemotherapy refer to 'systemic therapy.' If patient received platinum chemotherapy and anti-PD-1/PD-L1, refer to 'subsequent therapy.'"

**NSCL-27**
- Footnote tt added: "The data in the second-line setting suggest that PD-1/PD-L1 monotherapy is less effective, irrespective of PD-L1 expression, in **EGFR+/ALK+ NSCLC**." (also for NSLC-28)
- Footnote ggg added: "If progression on PD-1/PD-L1 inhibitor, switching to another PD-1/PD-L1 inhibitor is not routinely recommended." (also applies to NSCL-28, NSCL-J 2 of 4, NSCL-J 3 of 4)

**NSCL-A 1 of 4**
- Bullet 2 modified: "Formalin-fixed paraffin-embedded (FFPE) material is suitable for most molecular analyses, except bone biopsies that were previously treated with acid decalcifying solutions. Non-acid decalcification approaches may be successful for subsequent molecular testing. Many molecular pathology laboratories also accept cytopathology specimens such as direct smears or touch preparations. While many molecular pathology laboratories currently also accept cytopathology specimens such as cell blocks, direct smears, or touch preparations, laboratories that do not currently do so are strongly encouraged to identify approaches to testing on non-FFPE cytopathology specimens."

**NSCL-B 1 of 4**
- Evaluation, bullet 3 modified: "**For medically operable disease**, resection is the preferred local treatment modality (other modalities include SABR, thermal ablation such as radiofrequency ablation and cryotherapy). Thoracic surgical oncology consultation should be part of the evaluation of any patient being considered for curative local therapy. In cases where SABR is considered for high-risk or borderline operable patients, a multidisciplinary evaluation including a radiation oncologist is recommended."

**NSCL-C 1 of 10**
- General Principles; bullet 2, sentence 2 modified: "Radiation oncology input as part of a multidisciplinary evaluation or discussion should be provided for all patients with stage III NSCLC, early-stage disease who are medically inoperable, refuse surgery, or are high-risk surgical candidates, and stage IV disease that may benefit from local therapy."

**NSCL-C 2 of 10**
- Radiation Therapy Simulation, Planning, and Delivery; bullet 4 modified: "IGRT—including (but not limited to) orthogonal pair planar imaging and/or volumetric imaging (such as CBCT or CT on rails)—is recommended when using SABR, 3D-CRT/IMRT, and proton therapy with steep dose gradients around the target, when OARs are in close proximity to high-dose regions, and when using complex motion management techniques."
Updates in Version 1.2019 of the NCCN Guidelines for Non-Small Cell Lung Cancer from Version 6.2018 include:

**NSCL-C 3 of 10**

**General Treatment Information**

- **Early-Stage NSCLC (Stage I, selected node negative Stage IIA)**
  - Bullet 1 modified: "SABR (also known as SBRT) is recommended for patients who are medically inoperable or who refuse to have surgery after thoracic surgery evaluation. SABR has achieved good primary tumor control rates and overall survival, higher than conventionally fractionated radiotherapy, although not proven equivalent comparable to lobectomy and higher than 3D-CRT in nonrandomized and population-based comparisons in medically inoperable or older patients."
  - Bullet 2 modified: "SABR is also an appropriate option for patients with high surgical risk (able to tolerate sublobar resection but not lobectomy [eg, age ≥75 years], poor lung function). SABR and sublobar resection achieve comparable cancer-specific survival and primary tumor control."
  - Bullet removed: "A combined analysis of two randomized trials (that individually did not complete accrual) of SABR vs. lobectomy in operable patients found similar cancer-specific outcomes and improved toxicity profile and survival for SABR compared to surgery. This analysis does not provide sufficient data to change the standard of care for good surgical candidates but strengthens the indication for SABR in patients with relative contraindications for surgery or who refuse surgery."

- **SABR for Node-Negative Early-Stage NSCLC**
  - Dosing regimen; sentence added: "However, particular attention should be paid to tumors abutting the bronchial tree and esophagus to avoid severe toxicity."

**NSCL-C 4 of 10**

**Locally Advanced NSCLC (Stage II/III)**

- Bullet 1 modified: "Concurrent chemotherapy/RT is recommended for patients with inoperable stage II (node positive) and stage III NSCLC followed by consolidation durvalumab for stage III."
- Bullet removed: "RT has a role before or after surgery."
- Bullet 4 modified with the addition of this sentence: "RT should be planned up front such that it continues to a definitive dose without interruption if the patient does not proceed to surgery as initially planned."
- Bullet 7 modified: "Although the optimal sequence is not established, PORT is generally administered after postoperative chemotherapy with concurrent chemotherapy can be administered safely in medically fit patients and is recommended and concurrently with chemotherapy for positive resection margins."

**NSCL-C 5 of 10**

**Advanced/Metastatic NSCLC (Stage IV)**

- Bullet 2 modified: "Definitive RT to oligometastases (limited number is not universally defined but clinical trials have included up to 3–5 metastases), particularly SABR, is an appropriate option in such cases if it can be delivered safely to the involved sites. In 2 randomized phase II trials, significantly improved progression-free survival was found for local consolidative therapy (RT or surgery) to oligometastatic lesions versus maintenance systemic therapy or observation for patients not progressing on systemic therapy for local consolidative therapy."
- Bullet 3 added: "In the setting of progression at a limited number of sites on a given line of systemic therapy (oligoprogression), local ablative therapy to the oligoprogressive sites may extend the duration of benefit of the current line of systemic therapy."
- Bullet 4 added: "When treating oligometastatic/oligoprogressive lesions, if SABR is not feasible, other dose-intensive accelerated/hypofractionated conformal radiation therapy regimens may be used."
- **Palliative RT for Advanced Metastatic NSCLC**
  - Second sentence modified: "Shorter courses of RT are preferred for patients with poor performance status and/or shorter life expectancy because they provide similar pain relief as longer courses, although there is a higher potential need for retreatment, and are preferred for patients with poor performance status and/or shorter life expectancy."

**Continued**
Updates in Version 1.2019 of the NCCN Guidelines for Non-Small Cell Lung Cancer from Version 6.2018 include:

**NSCL-C 8 of 10**
- Table 5 title change to include "With Concurrent Chemotherapy"
  - Lung
    - V20 modified to ≤35–40%; V5 removed
  - Heart
    - V50 ≤25% added; V40, V45, V60 removed
    - Mean changed from ≤26 Gy to ≤20 Gy
  - Esophagus
    - V60 ≤17% added
    - "Contralateral sparing is desirable" added
  - Brachial plexus modified: "MaxMedian dose ≤6669 Gy"
- The following footnotes added:
  - "These constraints represent doses that generally should not be exceeded. Because the risk of toxicity increases progressively with dose to normal tissues, a key principle of radiation treatment planning is to keep normal tissue doses 'as low as reasonably achievable' while adequately covering the target. The doses to any given organ at risk should typically be lower than these constraints, approaching them only when there is close proximity to the target volume."
  - "Use V20 <35%, especially for the following: elderly ≥70 years, taxane chemotherapy, and poor PFTs (such as FEV1 or DLCO <50% normal). Use more conservative limits with a diagnosis or radiologic evidence of idiopathic pulmonary fibrosis (IPF)/usual interstitial pneumonia (UIP) (the tolerance of these patients is lower though not well characterized)."
- The following footnote removed: "RTOG 0617 data suggest that even lower radiation doses to the heart than previously appreciated may be detrimental to survival after thoracic RT, and more stringent constraints may be appropriate."

**NSCL-C 9 of 10 and NSCL-10 of 10**
- References 4, 19, 26, 42, 64, 90, 94 added.

**NSCL-G 1 of 5**
- Specimen Acquisition and Management; bullet 1 modified: "Although tumor testing has been primarily focused on use of formalin-fixed paraffin-embedded (FFPE) tissues, increasingly, laboratories accept other specimen types, notably cytology smear preparations not processed by FFPE methods. Although testing on cell blocks is not included in the FDA approval for multiple companion diagnostic assays, testing on these specimen types is highly recommended when it is the only or best material."
- Testing Methodologies; bullet 1 modified: "Next-generation sequencing (NGS) is increasingly utilized in clinical laboratories. Not all types of alterations are detected by individual NGS assays and it is important to be familiar with the types of alterations identifiable in individual assays or combination(s) of assays."

**NSCL-G 4 of 5**
- Bullet removed: "EGFR mutations: Limited mutation-specific antibodies are available for EGFR. While these antibodies have good specificity, the sensitivity is lacking, and it is not recommended to use EGFR mutation-specific antibodies except in circumstances of extremely limited tissue, because many sensitizing EGFR mutations are not detected with this approach."
Updates in Version 1.2019 of the NCCN Guidelines for Non-Small Cell Lung Cancer from Version 6.2018 include:

**NSCL-G 5 of 5**
- Section added:
  - "Plasma Cell-Free/Circulating Tumor DNA Testing:
    - Cell-free/circulating tumor DNA testing should not be used in lieu of a tissue diagnosis.
    - Some laboratories offer testing for molecular alterations examining nucleic acids in peripheral circulation, most commonly in processed plasma (sometimes referred to as 'liquid biopsy').
    - Studies have demonstrated cell-free tumor DNA testing to generally have very high specificity, but significantly compromised sensitivity, with up to 30% false-negative rate.
    - Standards for analytical performance characteristics of cell-free tumor DNA have not been established, and in contrast to tissue-based testing, no guidelines exist regarding the recommended performance characteristics of this type of testing.
    - Cell-free tumor DNA testing can identify alterations that are unrelated to a lesion of interest, for example, clonal hematopoiesis of indeterminate potential (CHIP).
    - The use of cell-free/circulating tumor DNA testing can be considered in specific clinical circumstances, most notably:
      - If a patient is medically unfit for invasive tissue sampling
      - In the initial diagnostic setting, if following pathologic confirmation of a NSCLC diagnosis there is insufficient material for molecular analysis, cell-free/circulating tumor DNA should be used only if follow-up tissue-based analysis is planned for all patients in which an oncogenic driver is not identified"

**NSCL-H**
- Title changed to "Emerging Biomarkers to Identify Patients for Therapies"
- "Tumor Mutation Burden" added
- Available Targeted Agents: "Nivolumab + ipilimumab and Nivolumab" added
- References 10, 11 added.
- Footnote added: "TMB is an evolving biomarker that may be helpful in selecting patients for immunotherapy. There is no consensus on how to measure TMB."

**NSCL-I 1 of 2**
- PD-L1 expression changed to PD-L1 \( \geq 50\% \)
  - First-line therapy
    - The following regimens added:
      - (Carboplatin or cisplatin)/pemetrexed/pembrolizumab (nonsquamous)
      - Carboplatin + paclitaxel/bevacizumab/atezolizumab (nonsquamous)
      - (Carboplatin or cisplatin)/paclitaxel or albumin-bound paclitaxel/pembrolizumab (squamous)
  - Subsequent therapy removed.
- Description of Maintenance Therapy Added.

**NSCL-I 2 of 2**
- References 3, 10, 25-27 added.
Updates in Version 1.2019 of the NCCN Guidelines for Non-Small Cell Lung Cancer from Version 6.2018 include:

NSCL-J 1 of 4

• Monitoring clarified as during initial therapy or during subsequent therapy

The following text removed:

• ADVANCED DISEASE
  ▶ The drug regimen with the highest likelihood of benefit with toxicity deemed acceptable to both the physician and the patient should be given as initial therapy for advanced lung cancer.
  ▶ Stage, weight loss, performance status, and gender predict survival.
  ▶ Platinum-based chemotherapy prolongs survival, improves symptom control, and yields superior quality of life compared to best supportive care.
  ▶ Histology of NSCLC is important in the selection of systemic therapy.
  ▶ Platinum combinations have generated a plateau in overall response rate (≈ 25%-35%), time to progression (4–6 mo), median survival (8–10 mo), 1-year survival rate (30%-40%), and 2-year survival rate (10%-15%) in fit patients.

• Initial Systemic Therapy
  ▶ There is superior efficacy and reduced toxicity for cisplatin/pemetrexed in patients with nonsquamous histology, in comparison to cisplatin/gemcitabine.
  ▶ There is superior efficacy for cisplatin/gemcitabine in patients with squamous histology, in comparison to cisplatin/pemetrexed.
  ▶ Two drug regimens are preferred; a third cytotoxic drug increases response rate but not survival. Single-agent therapy may be appropriate in select patients."

NSCL-J 2 of 4

• Categories added:
  ▶ "No contraindications to the addition of pembrolizumab or atezolizumab"
  ▶ "Contraindications to the addition of pembrolizumab or atezolizumab"

• The following regimens noted as preferred:
  ▶ (Carboplatin or cisplatin)/pemetrexed/pembrolizumab

• Footnote c added: "PD-1/PD-L1 contraindications may include active or previously documented autoimmune disease and/or current use of immunosuppressive agents or presence of an oncogene which would predict lack of benefit." (also applies to NSCL-J 3 of 4)

NSCL-J 3 of 4

• Categories added:
  ▶ No contraindications to the addition of pembrolizumab
  ▶ Contraindications to the addition of pembrolizumab

• The following regimens noted as category 1 and preferred:
  ▶ Pembrolizumab/carboplatin/(paclitaxel or albumin-bound paclitaxel)

• The following regimens added as category 2A:
  ▶ Pembrolizumab/cisplatin/(paclitaxel or albumin-bound paclitaxel)
LUNG CANCER PREVENTION AND SCREENING

- Lung cancer is a unique disease in that the major etiologic agent is an addictive product that is made and promoted by an industry. Approximately 85% to 90% of cases are caused by voluntary or involuntary (second-hand) cigarette smoking. Reduction of lung cancer mortality will require effective public health policies to prevent initiation of smoking, U.S. Food and Drug Administration (FDA) oversight of tobacco products, and other tobacco control measures.

- Persistent smoking is associated with second primary cancers, treatment complications, drug interactions, other tobacco-related medical conditions, diminished quality of life, and reduced survival.

- Reports from the Surgeon General on both active smoking (http://www.cdc.gov/tobacco/data_statistics/sgr/2004/pdfs/executivesummary.pdf) and second-hand smoke show that both cause lung cancer. The evidence shows a 20% to 30% increase in the risk for lung cancer from second-hand smoke exposure associated with living with a smoker (http://www.ncbi.nlm.nih.gov/books/NBK44324/).

- Every person should be informed of the health consequences, addictive nature, and mortal threat posed by tobacco consumption and exposure to tobacco smoke, and effective legislative, executive, administrative, or other measures should be contemplated at the appropriate governmental level to protect all persons from exposure to tobacco smoke (http://www.who.int/tobacco/framework/final_text/en/).

- Further complicating this problem, the delivery system of lung carcinogens also contains the highly addictive substance, nicotine. Reduction of lung cancer mortality will require widespread implementation of Agency for Healthcare Research and Quality (AHRQ) Guidelines (http://www.ahrq.gov/professionals/clinicians-providers/guidelines-recommendations/tobacco/index.html) to identify, counsel, and treat patients with nicotine habituation.

- Patients who are current or former smokers have significant risk for the development of lung cancer; chemoprevention agents are not yet established for these patients. When possible, these patients should be encouraged to enroll in chemoprevention trials.

- Lung cancer screening using low-dose CT (LDCT) is recommended in select high-risk smokers and former smokers (see the NCCN Guidelines for Lung Cancer Screening).

- See the NCCN Guidelines for Smoking Cessation.
Multidisciplinary evaluation including thoracic surgeons, thoracic radiologists, and pulmonologists to determine the likelihood of a cancer diagnosis and the optimal diagnostic or follow-up strategy.

Risk calculators can be used to quantify individual patient and radiologic factors but do not replace evaluation by a multidisciplinary diagnostic team with substantial experience in the diagnosis of lung cancer.

The most important radiologic factor is change or stability compared with a previous imaging study.

**Patient factors**
- Age
- Smoking history
- Previous cancer history
- Family history
- Occupational exposures
- Other lung disease (chronic obstructive pulmonary disease [COPD], pulmonary fibrosis)
- Exposure to infectious agents (e.g., endemic areas of fungal infections, tuberculosis) or risk factors or history suggestive of infection (e.g., immune suppression, aspiration, infectious respiratory symptoms)

**Radiologic factors**
- Size, shape, and density of the pulmonary nodule
- Associated parenchymal abnormalities (e.g., scarring or suspicion of inflammatory changes)
- Fluorodeoxyglucose (FDG) avidity on PET imaging

**Solid nodules**
See Follow-up (DIAG-2)

**Subsolid nodules**
See Follow-up (DIAG-3)

Lung nodules in asymptomatic, high-risk patients detected during lung cancer screening with LDCT

NCCN Guidelines for Lung Cancer Screening

---

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
### FINDINGS

- **Incidental finding: solid nodule(s) on chest CT**

#### FOLLOW-UP<sup>c,d,g,h</sup>

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Follow-up</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;6 mm</td>
<td>No routine follow-up</td>
</tr>
<tr>
<td>6–8 mm</td>
<td>CT at 6–12 mo → Stable → Consider CT at 18–24 mo</td>
</tr>
<tr>
<td>&gt;8 mm</td>
<td>Consider CT at 3 mo, PET/CT&lt;sup&gt;i,j&lt;/sup&gt; or biopsy</td>
</tr>
</tbody>
</table>

#### Low risk<sup>e</sup>

- CT at 12 mo (optional) → Stable → No routine follow-up

#### High risk<sup>f</sup>

- CT at 6–12 mo → Stable → Repeat CT at 18–24 mo

#### PET/CT<sup>i,j</sup>

- PET/CT performed skull base to knees or whole body. A positive PET result is defined as a standardized uptake value (SUV) in the lung nodule greater than the baseline mediastinal blood pool. A positive PET scan finding can be caused by infection or inflammation, including absence of lung cancer with localized infection, presence of lung cancer with associated (eg, postobstructive) infection, and presence of lung cancer with related inflammation (eg, nodal, parenchymal, pleural). A false-negative PET scan can be caused by a small nodule, low cellular density (nonsolid nodule or ground-glass opacity [GGO]), or low tumor avidity for FDG (eg, adenocarcinoma in situ [previously known as bronchoalveolar carcinoma], carcinoid tumor).

#### Biopsy</p>

- Patients with a suspicion of lung cancer after PET/CT require histologic confirmation before any nonsurgical therapy. When a biopsy is not possible, a multidisciplinary evaluation should be done including radiation oncology, surgery, and interventional pulmonology.

---

<sup>c</sup>See Principles of Diagnostic Evaluation (DIAG-A 1 of 3).

<sup>d</sup>The most important radiologic factor is change or stability compared with a previous imaging study.

<sup>e</sup>Low risk = minimal or absent history of smoking or other known risk factors.

<sup>f</sup>High risk = history of smoking or other known risk factors. Known risk factors include history of lung cancer in a first-degree relative; exposure to asbestos, radon, or uranium.

<sup>g</sup>Non-solid (ground-glass) nodules may require longer follow-up to exclude indolent adenocarcinoma.

<sup>h</sup>Adapted from Fleischner Society Guidelines; MacMahon H, Naidich DP, Goo JM, et al. Guidelines for management of incidental pulmonary nodules detected on CT images: From the Fleischer Society 2017. Radiology 2017;284:228-243. ©Radiological Society of North America. Fleischner Society Guidelines do not direct whether or not contrast is necessary or if an LDCT is appropriate. LDCT is preferred unless there is a reason for contrast enhancement for better diagnostic resolution.

<sup>i</sup>PET/CT performed skull base to knees or whole body. A positive PET result is defined as a standardized uptake value (SUV) in the lung nodule greater than the baseline mediastinal blood pool. A positive PET scan finding can be caused by infection or inflammation, including absence of lung cancer with localized infection, presence of lung cancer with associated (eg, postobstructive) infection, and presence of lung cancer with related inflammation (eg, nodal, parenchymal, pleural). A false-negative PET scan can be caused by a small nodule, low cellular density (nonsolid nodule or ground-glass opacity [GGO]), or low tumor avidity for FDG (eg, adenocarcinoma in situ [previously known as bronchoalveolar carcinoma], carcinoid tumor).

<sup>j</sup>Patients with a suspicion of lung cancer after PET/CT require histologic confirmation before any nonsurgical therapy. When a biopsy is not possible, a multidisciplinary evaluation should be done including radiation oncology, surgery, and interventional pulmonology.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
PRINCIPLES OF DIAGNOSTIC EVALUATION

• Patients with a strong clinical suspicion of stage I or II lung cancer (based on risk factors and radiologic appearance) do not require a biopsy before surgery.
  ‣ A biopsy adds time, costs, and procedural risk and may not be needed for treatment decisions.
  ‣ A preoperative biopsy may be appropriate if a non-lung cancer diagnosis is strongly suspected that can be diagnosed by core biopsy or fine-needle aspiration (FNA).
  ‣ A preoperative biopsy may be appropriate if an intraoperative diagnosis appears difficult or very risky.
  ‣ If a preoperative tissue diagnosis has not been obtained, then an intraoperative diagnosis (i.e., wedge resection, needle biopsy) is necessary before lobectomy, bilobectomy, or pneumonectomy.
• Bronchoscopy should preferably be performed during the planned surgical resection, rather than as a separate procedure.
  ‣ Bronchoscopy is required before surgical resection (see NSCL-2).
  ‣ A separate bronchoscopy may not be needed for treatment decisions before the time of surgery and adds time, costs, and procedural risk.
  ‣ A preoperative bronchoscopy may be appropriate if a central tumor requires pre-resection evaluation for biopsy, surgical planning (e.g., potential sleeve resection), or preoperative airway preparation (e.g., coring out an obstructive lesion).
• Invasive mediastinal staging is recommended before surgical resection for most patients with clinical stage I or II lung cancer (see NSCL-2).
  ‣ Patients should preferably undergo invasive mediastinal staging (mediastinoscopy) as the initial step before the planned resection (during the same anesthetic procedure), rather than as a separate procedure. For patients undergoing endobronchial ultrasound (EBUS)/endoscopic ultrasound (EUS) staging, this may require a separate procedure to allow evaluation if onsite rapid cytology interpretation is not available.
  ‣ A separate staging procedure adds time, costs, coordination of care, inconvenience, and an additional anesthetic risk.
  ‣ Preoperative invasive mediastinal staging may be appropriate for a strong clinical suspicion of N2 or N3 nodal disease or when intraoperative cytology or frozen section analysis is not available.
• In patients with suspected non-small cell lung cancer (NSCLC), many techniques are available for tissue diagnosis.
  ‣ Diagnostic tools that should be routinely available include:
    ◊ Sputum cytology
    ◊ Bronchoscopy with biopsy and transbronchial needle aspiration (TBNA)
    ◊ Image-guided transthoracic needle core biopsy (preferred) or FNA
    ◊ Thoracentesis
    ◊ Mediastinoscopy
    ◊ Video-assisted thoracic surgery (VATS) and open surgical biopsy
  ‣ Diagnostic tools that provide important additional strategies for biopsy include:
    ◊ EBUS–guided biopsy
    ◊ EUS–guided biopsy
    ◊ Navigational bronchoscopy
• The preferred diagnostic strategy for an individual patient depends on the size and location of the tumor, the presence of mediastinal or distant disease, patient characteristics (such as pulmonary pathology and/or other significant comorbidities), and local experience and expertise.

Factors to be considered in choosing the optimal diagnostic step include:

◊ Anticipated diagnostic yield (sensitivity)
◊ Diagnostic accuracy including specificity and particularly the reliability of a negative diagnostic study (ie, true negative)
◊ Adequate volume of tissue specimen for diagnosis and molecular testing
◊ Invasiveness and risk of procedure
◊ Efficiency of evaluation
  – Access and timeliness of procedure
    – Concomitant staging is beneficial, because it avoids additional biopsies or procedures. It is preferable to biopsy the pathology that would confer the highest stage (ie, to biopsy a suspected metastasis or mediastinal lymph node rather than the pulmonary lesion). Therefore, PET imaging is frequently best performed before a diagnostic biopsy site is chosen in cases of high clinical suspicion for aggressive, advanced-stage tumors.
◊ Technologies and expertise available
◊ Tumor viability at proposed biopsy site from PET imaging.

Decisions about the optimal diagnostic steps for suspected stage I to III lung cancer should be made by thoracic radiologists, interventional radiologists, and board-certified thoracic surgeons who devote a significant portion of their practice to thoracic oncology. Multidisciplinary evaluation should also include a pulmonologist or thoracic surgeon with expertise in advanced bronchoscopic techniques for diagnosis.
The least invasive biopsy with the highest yield is preferred as the first diagnostic study.

◊ Patients with central masses and suspected endobronchial involvement should undergo bronchoscopy.
◊ Patients with peripheral (outer one-third) nodules may benefit from navigational bronchoscopy, radial EBUS, or transthoracic needle aspiration (TTNA).
◊ Patients with suspected nodal disease should be biopsied by EBUS, EUS, navigational bronchoscopy, or mediastinoscopy.
  – EBUS provides access to nodal stations 2R/2L, 4R/4L, 7, 10R/10L, and other hilar nodal stations if necessary.
  – An EBUS-TBNA negative for malignancy in a clinically (PET and/or CT) positive mediastinum should undergo subsequent mediastinoscopy prior to surgical resection.
  – EUS–guided biopsy provides additional access to stations 5, 7, 8, and 9 lymph nodes if these are clinically suspicious.
  – TTNA and anterior mediastinotomy (ie, Chamberlain procedure) provide additional access to anterior mediastinal (stations 5 and 6) lymph nodes if these are clinically suspicious. If TTNA is not possible due to proximity to aorta, VATS biopsy is also an option.
◊ EUS also provides reliable access to the left adrenal gland.
◊ Lung cancer patients with an associated pleural effusion should undergo thoracentesis and cytology. A negative cytology result on initial thoracentesis does not exclude pleural involvement. An additional thoracentesis and/or thoracoscopic evaluation of the pleura should be considered before starting curative intent therapy.
◊ Patients suspected of having a solitary site of metastatic disease should have tissue confirmation of that site if feasible.
◊ Patients suspected of having metastatic disease should have confirmation from one of the metastatic sites if feasible.
◊ Patients who may have multiple sites of metastatic disease—based on a strong clinical suspicion—should have biopsy of the primary lung lesion or mediastinal lymph nodes if it is technically difficult or very risky to biopsy a metastatic site.

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
### Initial Evaluation

**NSCLC**

---

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

---

*a* T3, N0 related to size or satellite nodules.

*b* Testing is not listed in order of priority and is dependent on clinical circumstances, institutional processes, and judicious use of resources.

*c* Methods for evaluation include mediastinoscopy, mediastinotomy, EBUS, EUS, and CT-guided biopsy. An EBUS-TBNA negative for malignancy in a clinically (PET and/or CT) positive mediastium should undergo subsequent mediastinoscopy prior to surgical resection.

*d* There is low likelihood of positive mediastinal lymph nodes when these nodes are CT and PET negative in solid tumors <1 cm and purely non-solid tumors <3 cm. Thus, pre-resection pathologic mediastinal evaluation is optional in these settings.

*e* PET/CT performed skull base to knees or whole body. Positive PET/CT scan findings for distant disease need pathologic or other radiologic confirmation. If PET/CT scan is positive in the mediastinum, lymph node status needs pathologic confirmation.

*f* If MRI is not possible, CT of head with contrast.

*g* See Principles of Surgical Therapy (NSCL-B).

*h* See Principles of Radiation Therapy (NSCL-C).

*i* Interventional radiology ablation is an option for selected patients.

*j* After surgical evaluation, patients likely to receive adjuvant chemotherapy may be treated with induction chemotherapy as an alternative.

*k* See Chemotherapy Regimens for Neoadjuvant and Adjuvant Therapy (NSCL-D).

*l* Examples of high-risk factors may include poorly differentiated tumors (including lung neuroendocrine tumors [excluding well-differentiated neuroendocrine tumors]), vascular invasion, wedge resection, tumors >4 cm, visceral pleural involvement, and unknown lymph node status (Nx). These factors independently may not be an indication and may be considered when determining treatment with adjuvant chemotherapy.

*m* See Chemotherapy Regimens Used with Radiation Therapy (NSCL-E).

\(^{u}\)Consider RT boost if chemoradiation is given as initial treatment.

Note: All recommendations are category 2A unless otherwise indicated. Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
Methods for evaluation include mediastinoscopy, mediastinotomy, EBUS, EUS, and CT-guided biopsy. PET/CT performed skull base to knees or whole body. Positive PET/CT scan findings for distant disease need pathologic or other radiologic confirmation. If PET/CT scan is positive in the mediastinum, lymph node status needs pathologic confirmation. If MRI is not possible, CT of head with contrast.

Separate pulmonary nodule(s), same lobe (T3, N0-1) or ipsilateral non-primary lobe (T4, N0-1) → See Treatment (NSCL-9)

Stage IVA (N0, M1a): Contralateral lung (solitary nodule) → See Treatment (NSCL-9)

Extrathoracic metastatic disease → See Treatment for Metastasis limited sites (NSCL-13) or distant disease (NSCL-16)

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
After surgical evaluation, patients likely to receive adjuvant chemotherapy may be treated with induction chemotherapy as an alternative.

After surgical evaluation, patients likely to receive adjuvant chemotherapy may be treated with induction chemotherapy as an alternative.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
Lesions at low risk of becoming symptomatic can be observed (eg, small subsolid nodules with slow growth). However, if the lesion(s) becomes symptomatic or becomes high risk for producing symptoms (eg, subsolid nodules with accelerating growth or increasing solid component or increasing FDG uptake, even while small), treatment should be considered.

Lung-sparing resection is preferred, but tumor distribution and institutional expertise should guide individual treatment planning. Patients should be evaluated in a multidisciplinary setting (ie, surgery, radiation oncology, medical oncology).

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
**Stage IIIB (T1-2, N3)**
- PFTs (if not previously done)
- FDG PET/CT scan (if not previously done)
- Brain MRI with contrast
- Pathologic confirmation of N3 disease by:
  - Mediastinoscopy
  - Supraclavicular lymph node biopsy
  - Thoracoscopy
  - Needle biopsy
  - Mediastinotomy
  - EUS biopsy
  - EBUS biopsy

**Stage IIIC (T3, N3)**
- PFTs (if not previously done)
- FDG PET/CT scan (if not previously done)
- Brain MRI with contrast
- Pathologic confirmation of N3 disease by:
  - Mediastinoscopy
  - Supraclavicular lymph node biopsy
  - Thoracoscopy
  - Needle biopsy
  - Mediastinotomy
  - EUS biopsy
  - EBUS biopsy

\(i\)FDG PET/CT performed skull base to knees or whole body. Positive PET/CT scan findings for distant disease need pathologic or other radiologic confirmation. If PET/CT scan is positive in the mediastinum, lymph node status needs pathologic confirmation.

\(k\)If MRI is not possible, CT of head with contrast.

\(m\)See Principles of Radiation Therapy (NSCL-C).

\(r\)See Chemotherapy Regimens Used with Radiation Therapy (NSCL-E).

\(aa\)Most pleural (pericardial) effusions with lung cancer are a result of the tumor. In a few patients, however, multiple microscopic examinations of pleural (pericardial) fluid are negative for tumor, and fluid is non-bloody and not an exudate. If these elements and clinical judgment dictate that the effusion is not related to the tumor, the effusion should be excluded as a staging descriptor.
**Clinical Assessment**

**Initial Treatment**

PET/CT performed skull base to knees or whole body. Positive PET/CT scan findings for distant disease need pathologic or other radiologic confirmation. If PET/CT scan is positive in the mediastinum, lymph node status needs pathologic confirmation.

If MRI is not possible, CT of head with contrast.

Including selected patients with stage M1c and limited number and volume of metastatic lesions amenable to definitive local therapy. Limited number is undefined but clinical trials have included up to 3 to 5 metastases.

See NCCN Guidelines for Central Nervous System Cancers.

---

1PET/CT performed skull base to knees or whole body. Positive PET/CT scan findings for distant disease need pathologic or other radiologic confirmation. If PET/CT scan is positive in the mediastinum, lymph node status needs pathologic confirmation.

2If MRI is not possible, CT of head with contrast.

3Including selected patients with stage M1c and limited number and volume of metastatic lesions amenable to definitive local therapy. Limited number is undefined but clinical trials have included up to 3 to 5 metastases.

4See NCCN Guidelines for Central Nervous System Cancers.
TREATMENT OF THORACIC DISEASE

Definitive therapy for thoracic disease feasible

Consider systemic therapy (NSCL-17) and restaging to confirm non-progression or Proceed to definitive therapy

T1-3, N0

• Pathologic mediastinal nodal evaluation and
• Surgical resection or SABR

T1-3, N1

• Pathologic mediastinal nodal evaluation and
• Surgical resection or Definitive RT or Chemoradiation

Definitive local therapy for metastatic site, if not already given

Consider systemic therapy, if not already given (NSCL-17)

Definitive therapy for thoracic disease not feasible

T1-3, N2

T4, N0-2

Definitive chemoradiation

See Systemic Therapy for Metastatic Disease (NSCL-17)

Methods for evaluation include mediastinoscopy, mediastinotomy, EBUS, EUS, and CT-guided biopsy. See Principles of Surgical Therapy (NSCL-B).

See Principles of Radiation Therapy (NSCL-C).

See Chemotherapy Regimens Used with Radiation Therapy (NSCL-E).

Typically, RT (including SABR) or surgical resection.
SURVEILLANCE AFTER COMPLETION OF DEFINITIVE THERAPY

No evidence of clinical/radiographic disease

- Stage I–II (primary treatment included surgery ± chemotherapy)
  - H&P and chest CT ± contrast every 6 mo for 2–3 y, then H&P and a low-dose non–contrast-enhanced chest CT annually
- Stage I–II (primary treatment included RT) or stage III or stage IV (oligometastatic with all sites treated with definitive intent)
  - H&P and chest CT± contrast every 3–6 mo for 3 y, then H&P and chest CT © contrast every 6 mo for 2 y, then H&P and a low-dose non–contrast-enhanced chest CT annually
  - Residual or new radiographic abnormalities may require more frequent imaging
- Smoking cessation advice, counseling, and pharmacotherapy
- PET/CT or brain MRI is not routinely indicated
- See Cancer Survivorship Care (NSCL-F)

Locoregional recurrence

See Therapy for Recurrence and Metastasis (NSCL-16)

Distant metastases

See Therapy for Recurrence and Metastasis (NSCL-16)

Timing of CT scans within Guidelines parameters is a clinical decision.

FDG PET/CT is currently not warranted in the routine surveillance and follow-up of patients with NSCLC. However, many benign conditions (such as atelectasis, consolidation, and radiation fibrosis) are difficult to differentiate from neoplasm on standard CT imaging, and FDG PET/CT can be used to differentiate true malignancy in these settings. However, if FDG PET/CT is to be used as a problem-solving tool in patients after radiation therapy, histopathologic confirmation of recurrent disease is needed because areas previously treated with radiation therapy can remain FDG avid for up to 2 years.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
## THERAPY FOR RECURRENCE AND METASTASIS

### Locoregional recurrence or symptomatic local disease
- **Endobronchial obstruction**
- **Resectable recurrence**
- **Mediastinal lymph node recurrence**
  - No prior RT
  - Prior RT
- **Superior vena cava (SVC) obstruction**
- **Severe hemoptysis**

### Distant metastases
- **Localized symptoms**
- **Diffuse brain metastases**
- **Bone metastasis**
- **Limited metastasis**
- **Disseminated metastases**

### Any combination of the following:
- Laser/stent/other surgery
- External-beam RT or brachytherapy
- Photodynamic therapy
- Reresection (preferred)
- External-beam RT or SABR
- Concurrent chemoradiation
- Systemic therapy (NSCL-17)
- Concurrent chemoradiation (if not previously given) ± SVC stent
- External-beam RT ± SVC stent
- SVC stent
- Any combination of the following:
  - External-beam RT or brachytherapy
  - Laser or photodynamic therapy or embolization
  - Surgery
  - Chest CT with contrast
  - Brain MRI with contrast
  - PET/CT

### Evidence of disseminated disease
- Observation or Systemic therapy (NSCL-17) (category 2B)
- See Systemic Therapy for Metastatic Disease (NSCL-17)

### No evidence of disseminated disease
- Systemic therapy (NSCL-17) (category 2B)
- See Systemic Therapy for Metastatic Disease (NSCL-17)

### Palliative external-beam RT
- If risk of fracture, orthopedic stabilization + palliative external-beam RT
- Consider bisphosphonate therapy or denosumab

### See pathway for Stage IV, M1b (NSCL-13)
### See Systemic Therapy for Metastatic Disease (NSCL-17)

---

\(^k\)If MRI is not possible, CT of head with contrast.
\(^l\)See Principles of Surgical Therapy (NSCL-B).
\(^m\)See Principles of Radiation Therapy (NSCL-C).
\(^n\)Interventional radiology ablation is an option for selected patients.
\(^r\)See Chemotherapy Regimens Used with Radiation Therapy (NSCL-E).
\(^cc\)See NCCN Guidelines for Central Nervous System Cancers.

---

**Note:** All recommendations are category 2A unless otherwise indicated. Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
**HISTOLOGIC SUBTYPE**

- Adenocarcinoma
- Large cell
- NSCLC not otherwise specified (NOS)

**TESTING**

- Molecular testing
  - EGFR mutation testing (category 1)
  - ALK testing (category 1)
  - ROS1 testing
  - BRAF testing
  - Testing should be conducted as part of broad molecular profiling
  - PD-L1 testing (category 1)

**TESTING RESULTS**

- Sensitizing EGFR mutation positive (see NSCL-18)
- ALK positive (see NSCL-21)
- ROS1 positive (see NSCL-24)
- BRAF V600E positive (see NSCL-25)
- PD-L1 ≥1% and EGFR, ALK negative or unknown (see NSCL-27)
- EGFR, ALK, ROS1, BRAF negative or unknown, PD-L1 <1% or unknown (see NSCL-28)
  - Sensitizing EGFR mutation positive (see NSCL-18)
  - ALK positive (see NSCL-21)
  - ROS1 positive (see NSCL-24)
  - BRAF V600E positive (see NSCL-25)
  - PD-L1 ≥1% and EGFR, ALK negative or unknown (see NSCL-27)
  - EGFR, ALK, ROS1, BRAF negative or unknown, PD-L1 <1% or unknown (see NSCL-29)

**CLINICAL PRESENTATION**

- Squamous cell carcinoma

---

**Note:** All recommendations are category 2A unless otherwise indicated.

SENSITIZING EGFR MUTATION POSITIVE

FIRST-LINE THERAPY

- **EGFR mutation discovered prior to first-line systemic therapy**
  - Osimertinib (preferred) (category 1)
  - Erlotinib (category 1)
  - Afatinib (category 1)
  - Gefitinib (category 1)
  - Dacomitinib (category 1)
  - Progression
  - See Subsequent Therapy (NSCL-20)
  - See Subsequent Therapy (NSCL-19)

- **EGFR mutation discovered during first-line systemic therapy**
  - Complete planned systemic therapy, including maintenance therapy, or interrupt, followed by osimertinib (preferred) or erlotinib or afatinib or gefitinib or dacomitinib
  - Progression
  - See Subsequent Therapy (NSCL-20)
  - See Subsequent Therapy (NSCL-19)

**Note:** All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
SENSITIZING EGFR MUTATION POSITIVE

**Asymptomatic**
- Progression on erlotinib, afatinib, gefitinib or dacomitinib
  - T790M testing

**Symptomatic**
- Brain
  - Isolated lesion
  - Systemic
  - Multiple lesions

**SUBSEQUENT THERAPY**
- Consider definitive local therapy (eg, SABR or surgery) for limited lesions
- Osimertinib (if T790M+) (category 1) or
- Continue erlotinib or afatinib or gefitinib or dacomitinib

**Progression**
- Progression, see Subsequent Therapy (NSCL-20)
- Progression, see therapy for multiple lesions, noted below

**Progression, see therapy** for multiple lesions, noted below

**Adenocarcinoma (NSCL-28) or Squamous Cell Carcinoma (NSCL-29)**

---

See Principles of Molecular and Biomarker Analysis (NSCL-G).
See Targeted Therapy for Advanced or Metastatic Disease (NSCL-I).
For performance status 0-4.
Beware of flare phenomenon in subset of patients who discontinue EGFR TKI. If disease flare occurs, restart EGFR TKI.
Plasma-based testing should be considered at progression on EGFR TKIs for the T790M mutation. If plasma-based testing is negative, tissue-based testing with rebiopsy material is strongly recommended. Practitioners may want to consider scheduling the biopsy concurrently with plasma testing referral.
Consider osimertinib (regardless of T790M status) or pulse erlotinib for progressive leptomeningeal disease.
In the randomized phase III trial of dacomitinib, patients with brain metastases were not eligible for enrollment. In the setting of brain metastases, consider other options.
Afatinib or cetuximab may be considered in patients with disease progression on EGFR TKI therapy.
The data in the second-line setting suggest that PD-1/PD-L1 inhibitor monotherapy is less effective, irrespective of PD-L1 expression, in EGFR+/ALK+ NSCLC.

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

Squamous cell carcinoma

PS 0-2

Pembrolizumab (category 1 and preferred if PD-L1 ≥50%) (category 2B if PD-L1 1-49%)\(^{bbb}\) or (Carboplatin or cisplatin) + paclitaxel or albumin-bound paclitaxel + pembrolizumab (carboplatin combination: [category 1 if PD-L1 ≥50%] [category 1 and preferred if PD-L1 1-49%])

Response or stable disease

Continuation maintenance\(^{mm}\)

• Pembrolizumab\(^{ccc,ggg}\)
  or Close observation

Progression

See Systemic Therapy or Subsequent Therapy,\(^{fff}\) Squamous Cell Carcinoma (NSCL-29)

\(^{hh}\) See Principles of Molecular and Biomarker Analysis (NSCL-G).

\(^{mm}\) See Targeted Therapy for Advanced or Metastatic Disease (NSCL-I).

\(^{aaa}\) Contraindications for treatment with PD-1/PD-L1 inhibitors may include active or previously documented autoimmune disease and/or current use of immunosuppressive agents or presence of an oncogene, which would predict lack of benefit. If there are contraindications, refer to NSCL-28 (adenocarcinoma) or NSCL-29 (squamous cell carcinoma).

\(^{bbb}\) Pembrolizumab monotherapy can be considered in PD-L1 1-49%, in patients with poor PS or other contraindications to combination chemotherapy.

\(^{ccc}\) If pembrolizumab monotherapy given.

\(^{ddd}\) If pembrolizumab/cisplatin/pemetrexed or pembrolizumab/cisplatin/pemetrexed given.

\(^{eee}\) If atezolizumab/cisplatin/paclitaxel/bevacizumab given.

\(^{fff}\) If patient has not received platinum-doublet chemotherapy, refer to “systemic therapy.” If patient received platinum chemotherapy and anti-PD-1/PD-L1, refer to “subsequent therapy.”

\(^{ggg}\) If pembrolizumab/(cisplatin or carboplatin)/(paclitaxel or albumin-bound paclitaxel) given.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
Systemic immune checkpoint inhibitors (preferred)\textsuperscript{c,tt,iii}
Nivolumab (category 1)
or pembrolizumab (category 1)\textsuperscript{iii}
or atezolizumab (category 1)\textsuperscript{ii}
or Other systemic therapy: xx
Docetaxel or pemetrexed or
gemcitabine or
ramucirumab + docetaxel

Best supportive care
See NCCN Guidelines for Palliative Care
SQUAMOUS CELL CARCINOMA

INITIAL SYSTEMIC THERAPY

Systemic immune checkpoint inhibitors (preferred)\(c,tt,iii\):
- Nivolumab (category 1)
- Pembrolizumab (category 1)\(jjj\)
- Atezolizumab (category 1)
- Other systemic therapy:xx
  - Docetaxel or gemcitabine or ramucirumab + docetaxel

Continuation maintenancehhh:
- Pembrolizumabggg
- Gemcitabine (category 2B)
- Switch maintenancehhh (category 2B)
  - Docetaxel
  - Close observation

Response or stable disease:
- Progressioniii,mmm
- See NCCN Guidelines for Palliative Care

Tumor response evaluationhhh:
- PS 0-2
- PS 3-4

Best supportive care:
- See NCCN Guidelines for Palliative Care

\(tt\)The data in the second-line setting suggest that PD-1/PD-L1 inhibitor monotherapy is less effective, irrespective of PD-L1 expression, in EGFR+/ALK+ NSCLC.

\(xx\)If not previously given.

\(ggg\)If pembrolizumab/(cisplatin or carboplatin)/(paclitaxel or albumin-bound paclitaxel) given.

\(hhh\)See Systemic Therapy for Advanced or Metastatic Disease (NSCL-J).

iiiIf progression on PD-1/PD-L1 inhibitor, switching to another PD-1/PD-L1 inhibitor is not routinely recommended.

jjjPembrolizumab is approved for patients with NSCLC tumors with PD-L1 expression levels ≥1%, as determined by an FDA-approved test.

mmmIf not already given, options for PS 0-2 include (nivolumab, pembrolizumab, or atezolizumab), docetaxel (category 2B), gemcitabine (category 2B), or ramucirumab + docetaxel (category 2B); options for PS 3-4 include best supportive care. Options for further progression are best supportive care or clinical trial.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
• Pathologic Evaluation

The purpose of the pathologic evaluation of NSCLC will vary depending on whether the sample 1) is a biopsy or cytology specimen intended for initial diagnosis in a case of suspected NSCLC; 2) is a resection specimen; or 3) is obtained for molecular evaluation in the setting of an established NSCLC diagnosis.

◊ In small biopsies or cytology specimens intended for initial diagnosis, the primary purpose is a) to make an accurate diagnosis using the 2015 WHO classification; and b) to preserve the tissue for molecular studies, especially if the patient has advanced-stage disease.
◊ In small biopsies of poorly differentiated carcinomas, the terms “non-small cell carcinoma (NSCC)" or "non-small cell carcinoma not otherwise specified (NSCC-NOS)” should be used as little as possible and only when a more specific diagnosis is not possible by morphology and/or special staining.
◊ The following terms are acceptable: "NSCC favor adenocarcinoma" and "NSCC favor squamous cell carcinoma." "NSCC-NOS" should be reserved only for cases in which immunohistochemical testing is uninformative or ambiguous (see section on immunohistochemistry).
◊ Preservation of material for molecular testing is critical. Efforts should be undertaken to minimize block reorientation and the number of immunohistochemistry stains for cases that cannot be classified on histologic examination alone (see section on immunohistochemistry).

In resection specimens, the primary purpose is a) to classify the histologic type; and b) to determine all staging parameters, as recommended by the American Joint Committee on Cancer (AJCC), including tumor size, extent of invasion, adequacy of surgical margins, and presence or absence of lymph node metastases.

◊ The number of involved lymph node stations should be documented since it has prognostic significance (AJCC 8th ed). Direct extension of the primary tumor into an adjacent lymph node is considered as nodal involvement.
◊ The AJCC, Union for International Cancer Control (UICC), and International Association for the Study of Lung Cancer (IASLC) recommend that at least six nodes are removed during surgical resection, three from N1 and three from N2 stations (ie, a representative node from each station) for accurate staging. All lobectomy specimens should be extensively dissected to search for involved lymph nodes.

◊ In small biopsies or cytology specimens—obtained for molecular testing in the context of an established diagnosis after progression on targeted therapies, the primary purpose is a) to confirm the original pathologic type with minimal use of tissue for immunohistochemistry only in suspected small cell carcinoma transformation or a different histology; and b) to preserve material for molecular analysis.

• Formalin-fixed paraffin-embedded (FFPE) material is suitable for most molecular analyses, except bone biopsies that were previously treated with acid decalcifying solutions. Non-acid decalcification approaches may be successful for subsequent molecular testing. While many molecular pathology laboratories currently also accept cytopathology specimens such as cell blocks, direct smears, or touch preparations, laboratories that do not currently do so are strongly encouraged to identify approaches to testing on non-FFPE cytopathology specimens.

1Non-small cell carcinomas (NSCC, without the L for lung) that show no clear adenocarcinoma or squamous cell carcinoma morphology or immunohistochemical markers are regarded as NSCC not otherwise specified (NOS). In this setting, it is recommended that pathologists use the term NSCC rather than NSCLC, because the lack of pneumocyte marker expression in small biopsies or cytology leaves open the possibility of a metastatic carcinoma and the determination of a lung primary must be established clinically after excluding other primary sites.

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
NSCLC Classification

The types of NSCLC are: adenocarcinoma, squamous cell carcinoma, adenosquamous carcinoma, large cell carcinoma, and sarcomatoid carcinoma.

Squamous cell carcinoma: A malignant epithelial tumor that either shows keratinization and/or intercellular bridges, or a morphologically undifferentiated NSCC that expresses immunohistochemical markers of squamous cell differentiation.

Adenocarcinoma:
- For small (<3 cm), resected lesions, determining extent of invasion is critical.
  - Adenocarcinoma in situ (AIS; formerly BAC): A small (≤3 cm) localized nodule with lepidic growth, mostly non-mucinous, although mucinous types can occur. Multiple synchronous AIS tumors can also occur.
  - Minimally invasive adenocarcinoma (MIA): A small (≤3 cm) solitary adenocarcinoma with a predominantly lepidic pattern and ≤5 mm invasion in greatest dimension. MIA is usually non-mucinous, but rarely may be mucinous. MIA is, by definition, solitary and discrete.
  - Invasive adenocarcinoma: A malignant epithelial tumor with glandular differentiation, mucin production, or pneumocyte marker expression. The tumors show an acinar, papillary, micropapillary, lepidic, or solid growth pattern, with either mucin or pneumocyte marker expression. After comprehensive histologic subtyping in 5%–10% increments, the tumors are classified according to their predominant pattern. The invasive adenocarcinoma component should be present in at least one focus measuring >5 mm in greatest dimension.
  - Invasive adenocarcinoma variants: invasive mucinous adenocarcinoma, colloid adenocarcinoma, fetal adenocarcinoma, and enteric adenocarcinoma.

Adenosquamous carcinoma: A carcinoma showing components of both squamous cell carcinoma and adenocarcinoma, with each component constituting at least 10% of the tumor. Definitive diagnosis requires a resection specimen, although it may be suggested based on findings in small biopsies, cytology, or excisional biopsies. Presence of any adenocarcinoma component in a biopsy specimen that is otherwise squamous should trigger molecular testing.

Large cell carcinoma: Undifferentiated NSCC that lacks the cytologic, architectural, and histochemical features of small cell carcinoma, adenocarcinoma, or squamous cell carcinoma. The diagnosis requires a thoroughly sampled resected tumor and cannot be made on non-resection or cytology specimens.

Sarcomatoid carcinoma is a general term that includes pleomorphic carcinoma, carcinosarcoma, and pulmonary blastoma. For this reason, it is best to use the specific term for these entities whenever possible rather than the general term.
- Pleomorphic carcinoma is a poorly differentiated NSCC that contains at least 10% spindle and/or giant cells or a carcinoma consisting only of spindle and giant cells. Spindle cell carcinoma consists of an almost pure population of epithelial spindle cells, while Giant cell carcinoma consists almost entirely of tumor giant cells.
- Carcinosarcoma is a malignant tumor that consists of a mixture of NSCC and sarcoma-containing heterologous elements (eg, rhabdomyosarcoma, chondrosarcoma, osteosarcoma).
- Pulmonary blastoma is a biphasic tumor that consists of fetal adenocarcinoma (typically low grade) and primitive mesenchymal stroma.
Immunohistochemistry

- Judicious use of immunohistochemistry is strongly recommended to preserve tissue for molecular testing, most notably in small specimens. When adenocarcinoma or squamous cell carcinomas are poorly differentiated, the defining morphologic criteria that would allow for specific diagnosis may be inconspicuous or absent. In this case, immunohistochemistry or mucin staining may be necessary to determine a specific diagnosis.
- In small specimens, a limited number of immunostains with one lung adenocarcinoma marker (TTF1, napsin A) and one squamous carcinoma marker (p40, p63) should suffice for most diagnostic problems. Virtually all tumors that lack squamous cell morphology and show co-expression of p63 and TTF1 are preferably classified as adenocarcinoma. A simple panel of TTF1 and p40 may be sufficient to classify most NSCC-NOS cases.
- Testing for NUT expression by immunohistochemistry should be considered in all poorly differentiated carcinomas that lack glandular differentiation or specific etiology, particularly in non-smokers or in patients presenting at a young age, for consideration of a pulmonary NUT carcinoma.
- Immunohistochemistry should be used to differentiate primary lung adenocarcinoma from squamous cell carcinoma, large cell carcinoma, metastatic carcinoma, and primary pleural mesothelioma (particularly for pleural specimens).
- Primary pulmonary adenocarcinoma:
  - In patients for whom the primary origin of the carcinoma is uncertain, an appropriate panel of immunohistochemical stains is recommended to assess for metastatic carcinoma to the lung.
  - TTF1 is a homeodomain-containing nuclear transcription protein of the Nkx2 gene family that is expressed in epithelial cells of the embryonal and mature lung and thyroid. TTF1 immunoreactivity is seen in primary pulmonary adenocarcinoma in the majority (70%–90%) of non-mucinous adenocarcinoma subtypes. Metastatic adenocarcinoma to the lung is nearly always negative for TTF1 except in metastatic thyroid malignancies, in which case thyroglobulin and PAX8 are also positive. Rare cases of TTF1 positivity in tumors of other organs (gynecologic tract, pancreatobiliary) have been noted, and may be dependent on the specific TTF1 clone utilized, stressing the importance of correlation with clinical and radiologic features.
  - Napsin A - an aspartic proteinase expressed in normal type II pneumocytes and in proximal and distal renal tubules - appears to be expressed in >80% of lung adenocarcinomas and may be a useful adjunct to TTF1.
  - The panel of TTF1 (or alternatively napsin A) and p40 (or alternatively p63) may be useful in refining the diagnosis to either adenocarcinoma or squamous cell carcinoma in small biopsy specimens previously classified as NSCC NOS.
**Immunohistochemistry**

- Immunohistochemistry should be used to confirm neuroendocrine differentiation when there is morphologic evidence of neuroendocrine morphology (e.g., speckled chromatin pattern, nuclear molding, peripheral palisading):
  - NCAM (CD56), chromogranin, and synaptophysin are used to identify neuroendocrine tumors in cases in which morphologic suspicion of neuroendocrine differentiation exists.
  - A panel of markers is useful, but one positive marker is enough if the staining is unambiguous in more than 10% of the tumor cells.
- **Malignant mesothelioma versus pulmonary adenocarcinoma**
  - The distinction between pulmonary adenocarcinoma and malignant mesothelioma (epithelioid type) can be made by correlation of the histology with the clinical impression, imaging studies, and a panel of immunomarkers.
  - Immunostains sensitive and specific for mesothelioma include WT-1, calretinin, CK5/6, and D2-40 (usually negative in adenocarcinoma).
  - Immunostains sensitive and specific for adenocarcinoma include pCEA, Claudin 4, TTF1, and napsin A (negative in mesothelioma). Other potentially useful markers that can be considered include B72.3, Ber-EP4, MOC31, and CD15, but these generally do not have the sensitivity and specificity of the above markers.
  - A pancytokeratin such as AE1/AE3 is also useful, as a negative result suggests the possibility of other tumors.
  - Other markers can be helpful in the differential diagnosis between mesothelioma and metastatic carcinoma, and will also help determine the tumor origin. Examples include markers for lung adenocarcinoma (TTF1, napsin A), breast carcinoma (ERα, PR, GCDFP15, mammaglobin), renal cell carcinoma (PAX8), papillary serous carcinoma (PAX8, PAX2, and ER), adenocarcinomas of the gastrointestinal tract (CDX2), and prostate cancer (NKX3.1). Additionally, p40 (or p63) is helpful for distinguishing epithelioid mesotheliomas with pseudosquamous morphology from squamous cell carcinomas.
**PRINCIPLES OF SURGICAL THERAPY**

**Evaluation**
- Determination of resectability, surgical staging, and *pulmonary resection should be performed by board-certified thoracic surgeons who perform lung cancer surgery as a prominent part of their practice*.
- CT and PET/CT used for staging should be within 60 days before proceeding with surgical evaluation.
- For medically operable disease, resection is the preferred local treatment modality (other modalities include SABR, thermal ablation such as radiofrequency ablation, and cryotherapy). Thoracic surgical oncology consultation should be part of the evaluation of any patient being considered for curative local therapy. In cases where SABR is considered for high-risk or borderline operable patients, a multidisciplinary evaluation including a radiation oncologist is recommended.
- The overall plan of treatment as well as needed imaging studies should be determined before any non-emergency treatment is initiated.
- Thoracic surgeons should actively participate in multidisciplinary discussions and meetings regarding lung cancer patients (e.g., multidisciplinary clinic and/or tumor board).
- Patients who are active smokers should be provided counseling and smoking cessation support (*NCCN Guidelines for Smoking Cessation*). While active smokers have a mildly increased incidence of postoperative pulmonary complications, these should not be considered a prohibitive risk for surgery. Surgeons should not deny surgery to patients solely due to smoking status, as surgery provides the predominant opportunity for prolonged survival in patients with early-stage lung cancer.

**Resection**
- Anatomic pulmonary resection is preferred for the majority of patients with NSCLC.
- Sublobar resection - Segmentectomy and wedge resection should achieve parenchymal resection margins ≥2 cm or ≥ the size of the nodule.
- Sublobar resection should also sample appropriate N1 and N2 lymph node stations unless not technically feasible without substantially increasing the surgical risk.
- Segmentectomy (preferred) or wedge resection is appropriate in selected patients for the following reasons:
  - Poor pulmonary reserve or other major comorbidity that contraindicates lobectomy
  - Peripheral nodule1 ≤2 cm with at least one of the following:
    - Pure AIS histology
    - Nodule has ≥50% ground-glass appearance on CT
    - Radiologic surveillance confirms a long doubling time (≥400 days)
- VATS or minimally invasive surgery (including robotic-assisted approaches) should be strongly considered for patients with no anatomic or surgical contraindications, as long as there is no compromise of standard oncologic and dissection principles of thoracic surgery.
- In high-volume centers with significant VATS experience, VATS lobectomy in selected patients results in improved early outcomes (i.e., decreased pain, reduced hospital length of stay, more rapid return to function, fewer complications) without compromise of cancer outcomes.
- Lung-sparing anatomic resection (sleeve lobectomy) is preferred over pneumonectomy, if anatomically appropriate and margin-negative resection is achieved.
- T3 (invasion) and T4 local extension tumors require en-bloc resection of the involved structure with negative margins. If a surgeon or center is uncertain about potential complete resection, consider obtaining an additional surgical opinion from a high-volume specialized center.
Margins and Nodal Assessment
• Surgical pathologic correlation is critical to assess apparent close or positive margins, as these may not represent true margins or may not truly represent areas of risk for local recurrence (e.g., medial surface of mainstem or bronchus intermedius when separate subcarinal lymph node dissection has been performed; pleural margin adjacent to aorta when no attachment to aorta is present).
• N1 and N2 node resection and mapping should be a routine component of lung cancer resections—a minimum of three N2 stations sampled or complete lymph node dissection.
• Formal ipsilateral mediastinal lymph node dissection is indicated for patients undergoing resection for stage IIIA (N2) disease.
• Complete resection requires free resection margins, systematic node dissection or sampling, and the highest mediastinal node negative for tumor. The resection is defined as incomplete whenever there is involvement of resection margins, unremoved positive lymph nodes, or positive pleural or pericardial effusions. A complete resection is referred to as R0, microscopically positive resection as R1, and macroscopic residual tumor as R2.
• Patients with pathologic stage II or greater should be referred to medical oncology for evaluation.
• Consider referral to a radiation oncologist for resected stage IIIA.

The Role of Surgery in Patients with Stage IIIA (N2) NSCLC
The role of surgery in patients with pathologically documented N2 disease remains controversial. Two randomized trials evaluated the role of surgery in this population, but neither showed an overall survival benefit with the use of surgery. However, this population is heterogeneous and the panel believes that these trials did not sufficiently evaluate the nuances present with the heterogeneity of N2 disease and the likely oncologic benefit of surgery in specific clinical situations.
• The presence or absence of N2 disease should be vigorously determined by both radiologic and invasive staging prior to the initiation of therapy since the presence of mediastinal nodal disease has a profound impact on prognosis and treatment decisions. (NSCL-1, NSCL-2, and NSCL-6)
• Patients with occult-positive N2 nodes discovered at the time of pulmonary resection should continue with the planned resection along with formal mediastinal lymph node dissection. If N2 disease is noted in patients undergoing VATS, the surgeon may consider stopping the procedure so that induction therapy can be administered before surgery; however, continuing the procedure is also an option.
• The determination of the role of surgery in a patient with N2-positive lymph nodes should be made prior to the initiation of any therapy by a multidisciplinary team, including a board-certified thoracic surgeon who has a major part of his/her practice dedicated to thoracic oncology.
• The presence of N2-positive lymph nodes substantially increases the likelihood of positive N3 lymph nodes. Pathologic evaluation of the mediastinum must include evaluation of the subcarinal station and contralateral lymph nodes. EBUS +/- EUS are additional techniques for minimally invasive pathologic mediastinal staging that are complementary to mediastinoscopy. Even when these modalities are employed it is important to have an adequate evaluation of the number of stations involved and biopsy and documentation of negative contralateral lymph node involvement prior to a final treatment decision.

The Role of Surgery in Patients with Stage IIIA (N2) NSCLC is continued on NSCL-B 3 of 4 through NSCL-B 4 of 4
The Role of Surgery in Patients with Stage IIIA (N2) NSCLC

- Repeat mediastinoscopy, while possible, is technically difficult and has a lower accuracy compared to primary mediastinoscopy. One possible strategy is to perform EBUS (± EUS) in the initial pretreatment evaluation and reserve mediastinoscopy for nodal restaging after neoadjuvant therapy.5
- Patients with a single lymph node smaller than 3 cm can be considered for a multimodality approach that includes surgical resection.1,6,7
- Restaging after induction therapy is difficult to interpret, but CT +/- PET should be performed to exclude disease progression or interval development of metastatic disease.
- Patients with negative mediastinum after neoadjuvant therapy have a better prognosis.7,8
- Neoadjuvant chemoradiotherapy is used in 50% of the NCCN Member Institutions, while neoadjuvant chemotherapy is used in the other 50%. Overall survival appears similar provided RT is given postoperatively, if not given preoperatively.5,9 Neoadjuvant chemoradiotherapy is associated with higher rates of pathologic complete response and negative mediastinal lymph nodes.10 However, that is achieved at the expense of higher rates of acute toxicity and increased cost.
- When neoadjuvant chemoradiotherapy is used with doses lower than those used for standard definitive therapy, all efforts should be made to minimize any possible breaks in radiotherapy for surgical evaluation. Treatment breaks of more than 1 week are considered unacceptable.
- When timely surgical evaluation is not available, the strategy of neoadjuvant chemoradiotherapy should not be used. Another option in individual cases, and with the agreement of the thoracic surgeon, is to complete definitive chemoradiotherapy prior to re-evaluation and consideration for surgery.11,12 If a surgeon or center is uncertain about the feasibility or safety of resection after definitive doses of radiation, consider obtaining an additional surgical opinion from a high-volume specialized center. These operations may also benefit from additional considerations of soft tissue flap coverage in the radiation field at the time of resection.
- Data from a large multi-institutional trial indicate that pneumonectomy after neoadjuvant chemoradiotherapy has unacceptable morbidity and mortality.2 However, it is not clear if this is also true with neoadjuvant chemotherapy alone. Further, many groups have challenged that cooperative group finding with single-institution experiences demonstrating safety of pneumonectomy after induction therapy.13-16 In addition, there is no evidence that adding RT to induction regimens for patients with operable stage IIIA (N2) disease improves outcomes compared to induction chemotherapy.17

A questionnaire was submitted to the NCCN Member Institutions in 2010 regarding their approach to patients with N2 disease. Their responses indicate the patterns of practice when approaching this difficult clinical problem.

- Would consider surgery in patients with one N2 lymph node station involved by a lymph node smaller than 3 cm: (90.5%)
- Would consider surgery with more than one N2 lymph node station involved, as long as no lymph node was bigger than 3 cm: (47.6%)
- Uses EBUS (+/- EUS) in the initial evaluation of the mediastinum: (80%)
- Uses pathologic evaluation of the mediastinum, after neoadjuvant therapy, to make a final decision before surgery: (40.5%)
- Would consider neoadjuvant therapy followed by surgery when a patient is likely, based on initial evaluation, to require a pneumonectomy: (54.8%)

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

PRINCIPLES OF RADIATION THERAPY

I. General Principles (see Table 1, Commonly Used Abbreviations in Radiation Therapy)

• Determination of the appropriateness of radiation therapy (RT) should be made by board-certified radiation oncologists who perform lung cancer RT as a prominent part of their practice.

• RT has a potential role in all stages of NSCLC, as either definitive or palliative therapy. Radiation oncology input as part of a multidisciplinary evaluation or discussion should be provided for all patients with stage III NSCLC, early-stage disease who are medically inoperable, refuse surgery, or are high-risk surgical candidates, and stage IV disease that may benefit from local therapy.

• The critical goals of modern RT are to maximize tumor control and to minimize treatment toxicity. A minimum technologic standard is CT-planned 3D-CRT.¹

• More advanced technologies are appropriate when needed to deliver curative RT safely. These technologies include (but are not limited to) 4D-CT and/or PET/CT simulation, IMRT/VMAT, IGRT, motion management, and proton therapy (https://www.astro.org/Daily-Practice/Reimbursement/Model-Policies/Model-Policies/). Nonrandomized comparisons of using advanced technologies demonstrate reduced toxicity and improved survival versus older techniques.²⁻⁴ In a prospective trial of definitive chemo/RT for patients with stage III NSCLC (RTOG 0617), IMRT was associated with a nearly 60% decrease (from 7.9% to 3.5%) in high-grade radiation pneumonitis as well as similar survival and tumor control outcomes despite a higher proportion of stage IIIB and larger treatment volumes compared to 3D-CRT;⁵ as such, IMRT is preferred over 3D-CRT in this setting.

• Centers using advanced technologies should implement and document modality-specific quality assurance measures. The ideal is external credentialing of both treatment planning and delivery such as required for participation in RTOG clinical trials employing advanced technologies. Useful references include the ACR Practice Parameters and Technical Standards (https://www.acr.org/~/media/ACR/Documents/PGTS/toc.pdf).

II. Radiation Therapy Simulation, Planning, and Delivery

• Simulation should be performed using CT scans obtained in the RT treatment position with appropriate immobilization devices. IV contrast with or without oral contrast is recommended for better target/organ delineation whenever possible in patients with central tumors or nodal disease. Because IV contrast can affect tissue heterogeneity correction calculations, density masking or use of a pre-contrast scan may be needed when intense enhancement is present.

• PET/CT significantly improves targeting accuracy,⁶ especially for patients with significant atelectasis and when IV CT contrast is contraindicated. A randomized trial of PET/CT versus CT-only RT planning demonstrated improved preemption of futile radical RT, decreased recurrences, and a trend toward improved overall survival with PET/CT RT planning.⁷ Given the potential for rapid progression of NSCLC,⁸,⁹ PET/CT should be obtained preferably within 4 weeks before treatment. It is ideal to obtain PET/CT in the treatment position.

• Tumor and organ motion, especially owing to breathing, should be assessed or accounted for at simulation. Options include fluoroscopy, inhale/exhale or slow scan CT, or, ideally, 4D-CT.
PRINCIPLES OF RADIATION THERAPY

II. Radiation Therapy Simulation, Planning, and Delivery (continued)

• Photon beam energy should be individualized based on the anatomic location of the tumors and beam paths. In general, photon energies between 4 to 10 MV are recommended for beams passing through low-density lung tissue before entering the tumor. When there is no air gap before the beam enters the tumor (such as for some large mediastinal tumors or tumors attached to the chest wall), higher energies may improve the dose distribution, especially when using a smaller number of fixed beam angles.

• Tissue heterogeneity correction and accurate dose calculation algorithms are recommended that account for buildup and lateral electron scatter effects in heterogeneous density tissues. Heterogeneity correction with simple pencil beam algorithms is not recommended.\(^{10}\)

• Respiratory motion should be managed when motion is excessive. This includes (but is not limited to) forced shallow breathing with abdominal compression, accelerator beam gating with the respiratory cycle, dynamic tumor tracking, active breathing control (ABC), or coaching/biofeedback techniques. If motion is minimal or the ITV is small, motion-encompassing targeting is appropriate. A useful resource for implementation of respiratory motion management is the report of AAPM Task Group 76.\(^{11}\)

• IGRT—including (but not limited to) orthogonal pair planar imaging and/or volumetric imaging (such as CBCT or CT on rails)—is recommended when using SABR, 3D-CRT/IMRT, and proton therapy with steep dose gradients around the target, when OARs are in close proximity to high-dose regions, and when using complex motion management techniques.

III. Target Volumes, Prescription Doses, and Normal Tissue Dose Constraints (See Tables 2–5 on NSCL-C 7 of 10 and NSCL-C 8 of 10)

• ICRU Reports 62 and 83 detail the current definitions of target volumes for 3D-RT and IMRT. GTV comprises the known extent of disease (primary and nodal) on imaging and pathologic assessment, CTV includes regions of presumed microscopic extent or dissemination, and PTV comprises the ITV (which includes margin for target motion) plus a setup margin for positioning and mechanical variability.

https://www.rtog.org/CoreLab/ContouringAtlases/LungAtlas.aspx

• PTV margin can be decreased by immobilization, motion management, and IGRT techniques.

• Consistent delineation of normal structures is critical for evaluating plans for safety. The RTOG consensus lung-contouring atlas is a useful resource. https://www.rtog.org/CoreLab/ContouringAtlases/LungAtlas.aspx

• Commonly used prescription doses and normal tissue dose constraints are summarized in Tables 2 through 5. These are based on published experience, ongoing trials, historical data, modeling, and empirical judgment.\(^{12,13}\) Useful references include the recent reviews of normal organ dose responses from the QUANTEC project.\(^{14-18}\) Because risk of normal organ toxicity increases with dose, doses to normal organs should be kept as low as reasonably achievable rather than simply meeting nominal constraints. This is generally facilitated by more advanced techniques to achieve better dose conformity.
**PRINCIPLES OF RADIATION THERAPY**

**IV. General Treatment Information**

**Early-Stage NSCLC (Stage I, selected node-negative Stage IIA)**

- SABR (also known as SBRT)\(^{19}\) is recommended for patients who are medically inoperable or who refuse to have surgery after thoracic surgery evaluation. SABR has achieved good primary tumor control rates and overall survival, and higher than conventionally fractionated radiotherapy, although not proven equivalent to lobectomy.\(^{20-26}\)
- SABR is also an appropriate option for patients with high surgical risk (able to tolerate sublobar resection but not lobectomy [eg, age ≥75 years], poor lung function).
- For institutions without an established SABR program, more modestly hypofractionated or dose-intensified conventionally fractionated 3D-CRT regimens are less preferred alternatives.\(^{29-31}\)

**SABR for Node-Negative Early-Stage NSCLC**

- The high-dose intensity and conformity of SABR require minimizing the PTV.

**Dosing regimen**

- For SABR, intensive regimens of BED ≥100 Gy are associated with significantly better local control and survival than less intensive regimens.\(^{32}\) In the United States, only regimens of ≤5 fractions meet the arbitrary billing code definition of SBRT, but slightly more protracted regimens are appropriate as well.\(^{32,33}\) For centrally located tumors (defined variably as within 2 cm of the proximal bronchial tree and/or abutting mediastinal pleura) and even ultra-central tumors (defined as abutting the proximal bronchial tree), 4 to 10 fraction risk-adapted SABR regimens appear to be effective and safe,\(^{34-37}\) while 54 to 60 Gy in 3 fractions is unsafe and should be avoided.\(^{38}\) However, particular attention should be paid to tumors abutting the bronchial tree and esophagus to avoid severe toxicity. The maximum tolerated dose for 5-fraction regimens was studied prospectively in RTOG 0813; preliminary results demonstrate no high-grade toxicities at 50 Gy in 5 fractions.\(^{39}\)
- SABR is most commonly used for tumors up to 5 cm in size, though selected larger isolated tumors can be treated safely if normal tissue constraints are respected.\(^{39,40}\)
- Prescription doses incompletely describe the actual delivered doses, which also strongly depend on how the dose is prescribed (to the isocenter vs. an isodose volume covering a proportion of the PTV), the degree of dose heterogeneity, whether tissue density heterogeneity corrections are used, and the type of dose calculation algorithm.\(^{10,41-42}\) All of these must be considered when interpreting or emulating regimens from prior studies.
LOCALLY ADVANCED NSCLC (Stage II-III)

- Concurrent chemotherapy/RT is recommended for patients with inoperable stage II (node-positive) and stage III NSCLC.\textsuperscript{43-46}
- RT interruptions and dose reductions for manageable acute toxicities should be avoided by employing supportive care.
- Sequential chemotherapy/RT or RT alone is appropriate for frail patients unable to tolerate concurrent therapy.\textsuperscript{47,48}
- Accelerated RT regimens may be beneficial, particularly if concurrent chemotherapy would not be tolerated (i.e., in a sequential or RT-only approach).\textsuperscript{49,50}
- Preoperative concurrent chemotherapy/RT is an option for patients with resectable stage IIIA (minimal N2 and treatable with lobectomy)\textsuperscript{51} and is recommended for resectable superior sulcus tumors.\textsuperscript{52,53} RT should be planned up front such that it continues to a definitive dose without interruption if the patient does not proceed to surgery as initially planned.
- Preoperative chemotherapy and postoperative RT is an alternative for patients with resectable stage IIIA.\textsuperscript{54,55} The optimal timing of RT in trimodality therapy (preoperative with chemotherapy or postoperative) is not established and is controversial.\textsuperscript{56,57}
- The determination of resectability in trimodality therapy should be made prior to initiation of all treatment. Upfront multidisciplinary consultation is particularly important when considering surgical treatment of patients with stage III NSCLC.
- In patients with clinical stage I/II upstaged surgically to N2+, PORT appears to improve survival significantly as an adjunct to postoperative chemotherapy in non-randomized analyses.\textsuperscript{58,59} Although the optimal sequence is not established, PORT is generally administered after postoperative chemotherapy and concurrently with chemotherapy for positive resection margins.\textsuperscript{60-63}
- PORT is not recommended for patients with pathologic stage N0-1 disease, because it has been associated with increased mortality, at least when using older RT techniques.\textsuperscript{64}

CONVENTIONALLY FRACTIONATED RT FOR LOCALLY ADVANCED NSCLC

- IFI omitting ENI allows tumor dose escalation and is associated with a low risk of isolated nodal relapse, particularly in a patient staged with PET/CT.\textsuperscript{65-69} Two randomized trials found improved survival for IFI versus ENI, possibly because it enabled dose escalation.\textsuperscript{70} IFI is reasonable in order to optimize definitive dosing to the tumor.\textsuperscript{71} IFI is reasonable in order to optimize definitive dosing to the tumor and/or decrease normal tissue toxicity.

DOSING REGIMENS

- The most commonly prescribed doses for definitive RT are 60 to 70 Gy in 2 Gy fractions. Doses of at least 60 Gy should be given.\textsuperscript{72} Dose escalation is associated with better survival in non-randomized comparisons in RT alone,\textsuperscript{73} sequential chemo/RT,\textsuperscript{74} or concurrent chemo/RT.\textsuperscript{75} While optimal RT dose intensification remains a valid question, higher doses of 74 Gy are not currently recommended for routine use.\textsuperscript{76-80} A meta-analysis demonstrated improved survival with accelerated fractionation RT regimens,\textsuperscript{81} and individualized accelerated RT dose intensification is now being evaluated in a randomized trial (RTOG 1106).
PRINCIPLES OF RADIATION THERAPY

Conventionally Fractionated RT for Locally Advanced NSCLC (continued)

- **Dosing Regimens**
  - Doses of 45 to 54 Gy in 1.8 to 2 Gy fractions are standard preoperative doses. Definitive RT doses delivered as preoperative chemoRT can safely be administered and achieve promising nodal clearance and survival rates, but require experience in thoracic surgical techniques to minimize the risk of surgical complications after high-dose RT.
  - In PORT, the CTV includes the bronchial stump and high-risk draining lymph node stations. Standard doses after complete resection are 50 to 54 Gy in 1.8 to 2 Gy fractions, but a boost may be administered to high-risk regions including areas of nodal extracapsular extension or microscopic positive margins. Lung dose constraints should be more conservative, because tolerance appears to be reduced after surgery. The ongoing European LungART trial provides useful guidelines for PORT technique.

Advanced/Metastatic NSCLC (Stage IV)

- **RT is recommended for local palliation or prevention of symptoms (such as pain, bleeding, or obstruction).**
- **Definitive local therapy to isolated or limited metastatic sites (oligometastases) (including but not limited to brain, lung, and adrenal gland) achieves prolonged survival in a small proportion of well-selected patients with good performance status who have also received radical therapy to the intrathoracic disease.** Definitive RT to oligometastases (limited number is not universally defined but clinical trials have included up to 3–5 metastases), particularly SABR, is an appropriate option in such cases if it can be delivered safely to the involved sites. In 2 randomized phase II trials, significantly improved progression-free survival was found for local consolidative therapy (RT or surgery) to oligometastatic lesions versus maintenance systemic therapy or observation for patients not progressing on systemic therapy.
- In the setting of progression at a limited number of sites on a given line of systemic therapy (oligoprogression), local ablative therapy to the oligoprogressive sites may extend the duration of benefit of the current line of systemic therapy.
- **When treating oligometastatic/oligoprogressive lesions, if SABR is not feasible, other dose-intensive accelerated/hypofractionated conformal radiation therapy regimens may be used.**
- **See the NCCN Guidelines for Central Nervous System Cancers regarding RT for brain metastases.**

Palliative RT for Advanced/Metastatic NSCLC

- The dose and fractionation of palliative RT should be individualized based on goals of care, symptoms, performance status, and logistical considerations. Shorter courses of RT are preferred for patients with poor performance status and/or shorter life expectancy because they provide similar pain relief as longer courses, although there is a higher potential need for retreatment. For palliation of thoracic symptoms, higher dose/longer-course thoracic RT (eg, ≥30 Gy in 10 fractions) is associated with modestly improved survival and symptoms, particularly in patients with good performance status. When higher doses (>30 Gy) are warranted, technologies to reduce normal tissue irradiation (at least 3D-CRT and including IMRT or proton therapy as appropriate) may be used.

</tr>
</tbody>
</table>

Vxx = % of the whole OAR receiving ≥xx Gy.

*These constraints represent doses that generally should not be exceeded. Because the risk of toxicity increases progressively with dose to normal tissues, a key principle of radiation treatment planning is to keep normal tissue doses "as low as reasonably achievable" while adequately covering the target. The doses to any given organ at risk should typically be lower than these constraints, approaching them only when there is close proximity to the target volume.

†Use V20 <35%, especially for the following: elderly ≥70 years, taxane chemotherapy, and poor PFTs (such as FEV1 or DLCO <50% normal). Use more conservative limits with a diagnosis or radiologic evidence of idiopathic pulmonary fibrosis (IPF)/usual interstitial pneumonia (UIP) (the tolerance of these patients is lower though not well characterized).

**NCCN Guidelines for Central Nervous System Cancers**

Please note: Tables 2–5 provide doses and constraints used commonly or in past clinical trials as useful references rather than specific recommendations.

*Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.*

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

CHEMOTHERAPY REGIMENS FOR NEOADJUVANT AND ADJUVANT THERAPY

- **Cisplatin 50 mg/m² days 1 and 8; vinorelbine 25 mg/m² days 1, 8, 15, 22, every 28 days for 4 cycles** ¹
- **Cisplatin 100 mg/m² day 1; vinorelbine 30 mg/m² days 1, 8, 15, 22, every 28 days for 4 cycles** ², ³
- **Cisplatin 75–80 mg/m² day 1; vinorelbine 25–30 mg/m² days 1 + 8, every 21 days for 4 cycles**
- **Cisplatin 100 mg/m² day 1; etoposide 100 mg/m² days 1–3, every 28 days for 4 cycles** ²
- **Cisplatin 75 mg/m² day 1; gemcitabine 1250 mg/m² days 1, 8, every 21 days for 4 cycles** ⁴
- **Cisplatin 75 mg/m² day 1; docetaxel 75 mg/m² day 1 every 21 days for 4 cycles** ⁵
- **Cisplatin 75 mg/m² day 1, pemetrexed 500 mg/m² day 1 for nonsquamous every 21 days for 4 cycles** ⁶

Chemotherapy Regimens for Patients with Comorbidities or Patients Not Able to Tolerate Cisplatin

- **Carboplatin AUC 6 day 1, paclitaxel 200 mg/m² day 1, every 21 days for 4 cycles** ⁷
- **Carboplatin AUC 5 day 1, gemcitabine 1000 mg/m² days 1, 8, every 21 days for 4 cycles** ⁸
- **Carboplatin AUC 5 day 1, pemetrexed 500 mg/m² day 1 for nonsquamous every 21 days for 4 cycles** ⁹

All regimens can be used for sequential chemotherapy/RT.

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
CHEMOTHERAPY REGIMENS USED WITH RADIATION THERAPY

Concurrent Chemotherapy/RT Regimens

- Cisplatin 50 mg/m² on days 1, 8, 29, and 36; etoposide 50 mg/m² days 1–5, 29–33; concurrent thoracic RT¹,²,*,+¹
- Cisplatin 100 mg/m² days 1 and 29; vinblastine 5 mg/m²/weekly x 5; concurrent thoracic RT²,*,+¹
- Carboplatin AUC 5 on day 1, pemetrexed 500 mg/m² on day 1 every 21 days for 4 cycles; concurrent thoracic RT³ (nonsquamous)*,+¹
- Cisplatin 75 mg/m² on day 1, pemetrexed 500 mg/m² on day 1 every 21 days for 3 cycles; concurrent thoracic RT⁴,⁵ (nonsquamous)*,+¹ ± additional 4 cycles of pemetrexed 500 mg/m²+²
- Paclitaxel 45–50 mg/m² weekly; carboplatin AUC 2, concurrent thoracic RT⁶,*,+¹ ± additional 2 cycles every 21 days of paclitaxel 200 mg/m² and carboplatin AUC 6+¹

Consolidation Therapy for Patients with Unresectable Stage III NSCLC, PS 0-1, and No Disease Progression After 2 or More Cycles of Definitive Chemoradiation

Durvalumab 10 mg/kg IV every 2 weeks for up to 12 months⁷ (category 1)

*Regimens can be used as preoperative/adjuvant chemotherapy/RT.
†Regimens can be used as definitive concurrent chemotherapy/RT.
‡Durvalumab may be used after any of the concurrent chemo/RT regimens listed above for eligible patients.

CANCER SURVIVORSHIP CARE

NSCLC Long-term Follow-up Care
- Cancer Surveillance (See NSCL-15)
- Immunizations
  - Annual influenza vaccination
  - Herpes zoster vaccine
  - Pneumococcal vaccination with revaccination as appropriate
- See NCCN Guidelines for Survivorship

Counseling Regarding Health Promotion and Wellness
- Maintain a healthy weight
- Adopt a physically active lifestyle (Regular physical activity: 30 minutes of moderate-intensity physical activity on most days of the week)
- Consume a healthy diet with emphasis on plant sources
- Limit consumption of alcohol if one consumes alcoholic beverages

Additional Health Monitoring
- Routine blood pressure, cholesterol, and glucose monitoring
- Bone health: Bone density testing as appropriate
- Dental health: Routine dental examinations
- Routine sun protection

Resources
- National Cancer Institute Facing Forward: Life After Cancer Treatment

Cancer Screening Recommendations
- Colorectal Cancer:
  See NCCN Guidelines for Colorectal Cancer Screening
- Prostate Cancer:
  See NCCN Guidelines for Prostate Cancer Early Detection
- Breast Cancer:
  See NCCN Guidelines for Breast Cancer Screening

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
PRINCIPLES OF MOLECULAR AND BIOMARKER ANALYSIS

Molecular Diagnostic Studies in Non-Small Cell Lung Cancer

- Numerous gene alterations have been identified that impact therapy selection. Testing of lung cancer specimens for these alterations is important for identification of potentially efficacious targeted therapies, as well as avoidance of therapies unlikely to provide clinical benefit.
- Some selection approaches for targeted therapy include predictive immunohistochemical analyses, which are distinct from immunohistochemical studies utilized to identify tumor type and lineage.
- Major elements of molecular testing that are critical for utilization and interpretation of molecular results include:
  - Use of a laboratory that is properly accredited, with a minimum of CLIA accreditation
  - Understanding the methodologies that are utilized and the major limitations of those methodologies
  - Understanding the spectrum of alterations tested (and those not tested) by a specific assay
  - Knowledge of whether a tumor sample is subjected to pathologic review and tumor enrichment (ie, microdissection, macrodissection) prior to testing
  - The types of samples accepted by the testing laboratory
- Specimen Acquisition and Management:
  - Although tumor testing has been primarily focused on use of formalin-fixed paraffin-embedded (FFPE) tissues, increasingly, laboratories accept other specimen types, notably cytology preparations not processed by FFPE methods. Although testing on cell blocks is not included in the FDA approval for multiple companion diagnostic assays, testing on these specimen types is highly recommended when it is the only or best material.
  - A major limitation in obtaining molecular testing results for NSCLC occurs when minimally invasive techniques are used to obtain samples; the yield may be insufficient for molecular, biomarker, and histologic testing. Therefore, bronchoscopists and interventional radiologists should procure sufficient tissue to enable all appropriate testing.
  - When tissue is minimal, laboratories should deploy techniques to maximize tissue for molecular and ancillary testing, including dedicated histology protocols for small biopsies, including “up-front” slide sectioning for diagnostic and predictive testing.
- Testing Methodologies
  - Appropriate possible testing methodologies are indicated below for each analyte separately; however, several methodologies are generally considerations for use:
    ◊ Next-generation sequencing (NGS) is used in clinical laboratories. Not all types of alterations are detected by individual NGS assays and it is important to be familiar with the types of alterations identifiable in individual assays or combination(s) of assays.
    ◊ Real-time polymerase chain reaction (PCR) can be used in a highly targeted fashion (specific mutations targeted). When this technology is deployed, only those specific alterations that are targeted by the assay are assessed.
    ◊ Sanger sequencing requires the greatest degree of tumor enrichment. Unmodified Sanger sequencing is not appropriate for detection of mutations in tumor samples with less than 25% to 30% tumor after enrichment and is not appropriate for assays in which identification of subclonal events (eg, resistance mutations) is important. If Sanger sequencing is utilized, tumor enrichment methodologies are nearly always recommended.
    ◊ Other methodologies may be utilized, including multiplex approaches not listed above (ie, SNaPshot, MassARRAY).
    ◊ Fluorescence in situ hybridization (FISH) analysis is utilized for many assays examining copy number, amplification, and structural alterations such as gene rearrangements.
    ◊ Immunohistochemistry (IHC) is specifically utilized for some specific analytes, and can be a useful surrogate or screening assay for others.

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
Molecular Targets for Analysis

In general, the mutations/alterations described below are seen in a non-overlapping fashion, although between 1%–3% of NSCLC may harbor concurrent alterations.

**EGFR (Epidermal Growth Factor Receptor) Gene Mutations:** EGFR is a receptor tyrosine kinase normally found on the surface of epithelial cells and is often overexpressed in a variety of human malignancies.

◊ The most commonly described mutations in *EGFR* (exon 19 deletions, p.L858R point mutation in exon 21) are associated with responsiveness to EGFR tyrosine kinase inhibitor (TKI) therapy; most recent data indicate that tumors that do not harbor a sensitizing *EGFR* mutation should not be treated with EGFR TKI in any line of therapy.

◊ Many of the less commonly observed alterations in EGFR, which cumulatively account for ~10% of *EGFR*-mutated NSCLC (ie, exon 19 insertions, p.L861Q, p.G719X, p.S768I) are also associated with responsiveness to EGFR TKI therapy, although the number of studied patients is lower.

◊ Some mutations in *EGFR* are associated with lack of responsiveness to EGFR TKI therapy, including most *EGFR* exon 20 insertions, and p.T790M.
  – Most *EGFR* exon 20 insertion mutations predict resistance to clinically achievable levels of TKIs.
  – The exception is a rare *EGFR* exon 20 insertion variant, p.A763_Y764insFQEA, which is associated with responsiveness to EGFR TKI therapy. Therefore, knowledge of an *EGFR* exon 20 insertion must be included in the specific sequence alteration.
  – The finding of p.T790M is most commonly associated with relapse following initial therapy with EGFR TKI, which is a known mechanism of resistance. If identified prior to TKI exposure, genetic counseling should be considered, because germline p.T790M is associated with familial lung cancer predisposition and additional testing is warranted.

◊ As use of NGS testing increases, additional *EGFR* variants are increasingly identified; however, the clinical implications of individual alterations are unlikely to be well established.

◊ Some clinicopathologic features—such as smoking status, ethnicity, and histology—are associated with the presence of an *EGFR* mutation; however, these features should not be utilized in selecting patients for testing.

◊ Testing Methodologies: Real-time PCR, Sanger sequencing (ideally paired with tumor enrichment), and NGS are the most commonly deployed methodologies for examining *EGFR* mutation status.

**ALK (Anaplastic Lymphoma Kinase) Gene Rearrangements:** ALK is a receptor tyrosine kinase that can be rearranged in NSCLC, resulting in dysregulation and inappropriate signaling through the ALK kinase domain.

◊ The most common fusion partner seen with ALK is echinoderm microtubule-associated protein-like 4 (EML4), although a variety of other fusion partners have been identified.

◊ The presence of an *ALK* rearrangement is associated with responsiveness to ALK TKIs, with recent studies demonstrating improved efficacy of alectinib over crizotinib in the first-line setting.

◊ Some clinicopathologic features—such as smoking status and histology have been associated with the presence of an *ALK* rearrangement; however, these features should not be utilized in selecting patients for testing.

◊ Testing Methodologies: FISH break-apart probe methodology was the first methodology deployed widely. IHC can be deployed as an effective screening strategy. FDA-approved IHC (ALK [D5F3] CDx Assay) can be utilized as a stand-alone test, not requiring confirmation by FISH, although secondary confirmation is encouraged. Numerous NGS methodologies can detect *ALK* fusions, and targeted real-time PCR assays are utilized in some settings, although they are unlikely to detect fusions with novel partners.
**ROS1 (ROS proto-oncogene 1) Gene Rearrangements:** ROS1 is a receptor tyrosine kinase that can be rearranged in NSCLC, resulting in dysregulation and inappropriate signaling through the ROS1 kinase domain.
- Numerous fusion partners are seen with ROS1, and common fusion partners include: CD74, SLC34A2, CCDC6, and FIG.
- The presence of a ROS1 rearrangement is associated with responsiveness to oral ROS1 TKIs.
- Some clinicopathologic features—such as smoking status and histology—have been associated with the presence of a ROS1 rearrangement; however, these features should not be utilized in selecting patients for testing.
- Testing Methodologies: FISH break-apart probe methodology can be deployed; however, it may under-detect the FIG-ROS1 variant. IHC approaches can be deployed; however, IHC for ROS1 fusions has low specificity, and follow-up confirmatory testing is a necessary component of utilizing ROS1 IHC as a screening modality. Numerous NGS methodologies can detect ROS1 fusions, and targeted real-time PCR assays are utilized in some settings, although they are unlikely to detect fusions with novel partners (which may lead to under-detection of ROS1 fusion events).

**BRAF (B-Raf proto-oncogene) point mutations:** BRAF is a serine/threonine kinase that is part of the canonical MAP/ERK signaling pathway. Activating mutations in BRAF result in unregulated signaling through the MAP/ERK pathway.
- Mutations in BRAF can be seen in NSCLC. The presence of a specific mutation resulting in a change in amino acid position 600 (p.V600E) has been associated with combined therapy with oral inhibitors of BRAF and MEK.
- Note that other mutations in BRAF are observed in NSCLC, and the impact of those mutations on therapy selection is not well understood at this time.
- Testing Methodologies: Real-time PCR, Sanger sequencing (ideally paired with tumor enrichment), and NGS are the most commonly deployed methodologies for examining BRAF mutation status. While an anti-BRAF p.V600E-specific monoclonal antibody is commercially available, and some studies have examined utilizing this approach, it should only be deployed after extensive validation.

**KRAS (KRAS proto-oncogene) point mutations:** KRAS is a G-protein with intrinsic GTPase activity, and activating mutations result in unregulated signaling through the MAP/ERK pathway.
- Mutations in KRAS are most commonly seen at codon 12, although other mutations can be seen in NSCLC.
- The presence of a KRAS mutation is prognostic of poor survival when compared to patients with tumors without KRAS mutation.
- Mutations in KRAS have been associated with reduced responsiveness to EGFR TKI therapy.
- Owing to the low probability of overlapping targetable alterations, the presence of a mutation in KRAS may identify patients who will not benefit from further molecular testing.

**Testing in the Setting of Progression on Targeted Therapy:**
- For many of the above listed analytes, there is growing recognition of the molecular mechanisms of resistance to therapy. Re-testing of a sample that is actively progressing while exposed to targeted therapy can shed light on appropriate next therapeutic steps:
  - For patients with an underlying EGFR sensitizing mutation who have been treated with EGFR TKI, minimum appropriate testing includes high-sensitivity evaluation for p.T790M; when there is no evidence of p.T790M, testing for alternate mechanisms of resistance (MET amplification, ERBB2 amplification) may be used to direct patients for additional therapies. The presence of p.T790M can direct patients to third-generation EGFR TKI therapy.
• Testing in the Setting of Progression on Targeted Therapy (continued)
  – Assays for the detection of EGFR p.T790M should be designed to have an analytic sensitivity of a minimum of 5% allelic fraction. The original sensitizing mutation can be utilized as an internal control in many assays to determine whether a p.T790M is within the range of detection if present as a sub-clonal event.
  ◊ For patients with underlying ALK rearrangement who have been treated with ALK TKI, it is unclear whether identification of specific tyrosine kinase domain mutation can identify appropriate next steps in therapy, although some preliminary data suggest that specific kinase domain mutations can impact next line of therapy.

• IHC for Biomarker Selection in NSCLC:
  – PD-L1 (Programmed Death Ligand 1): PD-L1 is a co-regulatory molecule that can be expressed on tumor cells and inhibit T-cell–mediated cell death. T-cells express PD-1, a negative regulator, which binds to ligands including PD-L1 (CD274) or PD-L2 (CD273). In the presence of PD-L1, T-cell activity is suppressed.
  ◊ Checkpoint inhibitor antibodies block the PD-1 and PD-L1 interaction, thereby improving the antitumor effects of endogenous T cells.
  ◊ IHC for PD-L1 can be utilized to identify disease most likely to respond to first-line anti PD-1/PD-L1.
    – Various antibody clones have been developed for IHC analysis of PD-L1 expression, and while several show relative equivalence, some do not.
    – Interpretation of PD-L1 IHC is typically focused on the proportion of tumor cells expressing membranous staining at any level and therefore is a linear variable.
    – The FDA-approved IHC assay for PD-L1 utilizes a cutoff of 50% tumor proportion score for first-line and 1% tumor proportion score for second-line therapy with pembrolizumab.
    – The definition of positive and negative testing is dependent on the individual antibody and platform deployed, which may be unique to each checkpoint inhibitor therapy. The potential for multiple different assays for PD-L1 has raised concern among both pathologists and oncologists.
  – ALK fusions: IHC assays for ALK can serve as a screening modality for further ALK testing, and can alternatively be used as a stand-alone test to determine eligibility for ALK TKI. An FDA-approved IHC assay for ALK is available.
  – ROS1 fusions: IHC assays for ROS1 should only be deployed as a screening modality for further ROS1 testing, because the specificity of a positive result is low. Positive ROS1 IHC should not be utilized to select patients for TKI therapy without additional confirmatory testing. Currently there is not an FDA-approved IHC assay for ROS1.
  – BRAF p.V600E mutations: An antibody specific to the p.V600E mutation is available. Some studies have examined utilization of this antibody in cases of NSCLC; however, optimization of this antibody may be tumor-specific and care should be exercised when using this approach.
PRINCIPLES OF MOLECULAR AND BIOMARKER ANALYSIS

• Plasma Cell-Free/Circulating Tumor DNA Testing:
  ▶ Cell-free/circulating tumor DNA testing should not be used in lieu of a tissue diagnosis.
  ▶ Some laboratories offer testing for molecular alterations examining nucleic acids in peripheral circulation, most commonly in processed plasma (sometimes referred to as "liquid biopsy").
  ▶ Studies have demonstrated cell-free tumor DNA testing to generally have very high specificity, but significantly compromised sensitivity, with up to 30% false-negative rate.
  ▶ Standards for analytical performance characteristics of cell-free tumor DNA have not been established, and in contrast to tissue-based testing, no guidelines exist regarding the recommended performance characteristics of this type of testing.
  ▶ Cell-free tumor DNA testing can identify alterations that are unrelated to a lesion of interest, for example, clonal hematopoiesis of indeterminate potential (CHIP).
  ▶ The use of cell-free/circulating tumor DNA testing can be considered in specific clinical circumstances, most notably:
    ◊ If a patient is medically unfit for invasive tissue sampling
    ◊ In the initial diagnostic setting, if following pathologic confirmation of a NSCLC diagnosis there is insufficient material for molecular analysis, cell-free/circulating tumor DNA should be used only if follow-up tissue-based analysis is planned for all patients in which an oncogenic driver is not identified

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
## EMERGING BIOMARKERS TO IDENTIFY NOVEL THERAPIES FOR PATIENTS WITH METASTATIC NSCLC

<table>
<thead>
<tr>
<th>Genetic Alteration (ie, Driver event)</th>
<th>Available Targeted Agents with Activity Against Driver Event in Lung Cancer</th>
</tr>
</thead>
<tbody>
<tr>
<td>High-level MET amplification or MET exon 14 skipping mutation</td>
<td>Crizotinib&lt;sup&gt;1-5&lt;/sup&gt;</td>
</tr>
<tr>
<td>RET rearrangements</td>
<td>Cabozantinib&lt;sup&gt;6,7&lt;/sup&gt;</td>
</tr>
<tr>
<td>ERBB2 (HER2) mutations</td>
<td>Ado-trastuzumab emtansine&lt;sup&gt;9&lt;/sup&gt;</td>
</tr>
<tr>
<td>Tumor mutational burden (TMB)*</td>
<td>Nivolumab + ipilimumab&lt;sup&gt;10&lt;/sup&gt;</td>
</tr>
</tbody>
</table>

*TMB is an evolving biomarker that may be helpful in selecting patients for immunotherapy. There is no consensus on how to measure TMB.

---

### Note:
All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
TARGETED THERAPY FOR ADVANCED OR METASTATIC DISEASE

Monitoring During Initial Therapy

• Response assessment after 2 cycles, then every 2–4 cycles with CT of known sites of disease with or without contrast or when clinically indicated.

Monitoring During Subsequent Therapy

• Response assessment with CT of known sites of disease with or without contrast every 6–12 weeks. Timing of CT scans within Guidelines parameters is a clinical decision.

Sensitizing EGFR Mutation Positive

• First-line therapy
  ‣ Afatinib1
  ‣ Erlotinib2
  ‣ Dacomitinib3
  ‣ Gefitinib4,5
  ‣ Osimertinib6
• Subsequent therapy
  ‣ Osimertinib7

ALK Rearrangement Positive

• First-line therapy
  ‣ Alectinib8,9
  ‣ Brigatinib10
  ‣ Ceritinib11
  ‣ Crizotinib8,12
• Subsequent therapy
  ‣ Alectinib13,14
  ‣ Brigatinib15
  ‣ Ceritinib16
  ‣ Lorlatinib17

ROS1 Rearrangement Positive

• First-line therapy
  ‣ Ceritinib18
  ‣ Crizotinib19

BRAF V600E Mutation Positive

• First-line therapy
  ‣ Dabrafenib/trametinib20
• Subsequent therapy
  ‣ Dabrafenib/trametinib21,22

NTRK Gene Fusion Positive

• First-line/Subsequent therapy
  ‣ Larotrectinib23

PD-L1 ≥1%

• First-line therapy*
  ‣ Pembrolizumab24,25,26
  ‣ (Carboplatin or cisplatin)/pemetrexed/pembrolizumab (non-squamous)27
  ‣ Carboplatin/paclitaxel/bevacizumab/atezolizumab (nonsquamous)28
  ‣ (Carboplatin or cisplatin)/(paclitaxel or albumin-bound paclitaxel)/pembrolizumab (squamous)29

*Continuation maintenance refers to the use of at least one of the agents given in first line, beyond 4–6 cycles, in the absence of disease progression.

References

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
TARGETED THERAPY FOR ADVANCED OR METASTATIC DISEASE

SYSTEMIC THERAPY FOR ADVANCED OR METASTATIC DISEASE

Monitoring During Initial Therapy

- Response assessment after 2 cycles, then every 2–4 cycles with CT of known sites of disease with or without contrast or when clinically indicated.

Maintenance Therapy

- Continuation maintenance refers to the use of at least one of the agents given in first line, beyond 4–6 cycles, in the absence of disease progression. Switch maintenance refers to the initiation of a different agent, not included as part of the first-line regimen, in the absence of disease progression, after 4–6 cycles of initial therapy.

Monitoring During Subsequent Therapy

- Response assessment with CT of known sites of disease with or without contrast every 6–12 weeks. Timing of CT scans within Guidelines parameters is a clinical decision.

See Initial Systemic Therapy Options for Adenocarcinoma, Large cell, NSCLC NOS on NSCL-J (2 of 4)

See Initial Systemic Therapy Options for Squamous Cell Carcinoma on NSCL-J (3 of 4)
Initial Systemic Therapy Options

**Adenocarcinoma, Large Cell, NSCLC NOS (PS 0-1)**

- No contraindications to the addition of pembrolizumab or atezolizumab
  - Pembrolizumab/carboplatin/pemetrexed (category 1)\(^1,2,d\) (preferred)
  - Pembrolizumab/cisplatin/pemetrexed (category 1)\(^2,d\) (preferred)
  - Atezolizumab/carboplatin/paclitaxel/bevacizumab (category 1)\(^3,d,e,f,g\)

**Contraindications to the addition of pembrolizumab or atezolizumab**

- Bevacizumab/carboplatin/paclitaxel (category 1)\(^4,e,f,g\)
- Bevacizumab/carboplatin/pemetrexed\(^4,e,f,g\)
- Bevacizumab/cisplatin/pemetrexed\(^6,e,f,g\)
- Carboplatin/albumin-bound paclitaxel (category 1)\(^7\)
- Carboplatin/docetaxel (category 1)\(^8\)
- Carboplatin/etoposide (category 1)\(^9,10\)
- Carboplatin/gemcitabine (category 1)\(^11\)
- Carboplatin/paclitaxel (category 1)\(^12\)
- Carboplatin/pemetrexed (category 1)\(^13\)
- Cisplatin/docetaxel (category 1)\(^8\)
- Cisplatin/etoposide (category 1)\(^14\)
- Cisplatin/gemcitabine (category 1)\(^12,15\)
- Cisplatin/paclitaxel (category 1)\(^16\)
- Cisplatin/pemetrexed (category 1)\(^15\)
- Gemcitabine/docetaxel (category 1)\(^17\)
- Gemcitabine/vinorelbine (category 1)\(^18\)

**Adenocarcinoma, Large Cell, NSCLC NOS (PS 2)**

- Albumin-bound paclitaxel\(^19\)
- Carboplatin/albun-bound paclitaxel\(^20,21\)
- Carboplatin/docetaxel\(^8\)
- Carboplatin/etoposide\(^9,10\)
- Carboplatin/gemcitabine\(^11\)
- Carboplatin/paclitaxel\(^12\)
- Carboplatin/pemetrexed\(^13\)
- Docetaxel\(^22,23\)
- Gemcitabine\(^24-26\)
- Gemcitabine/docetaxel\(^17\)
- Gemcitabine/vinorelbine\(^18\)
- Paclitaxel\(^27-29\)
- Pemetrexed\(^30\)

---

\(^a\) Albumin-bound paclitaxel may be substituted for either paclitaxel or docetaxel in patients who have experienced hypersensitivity reactions after receiving paclitaxel or docetaxel despite premedication, or for patients where the standard premedications (i.e., dexamethasone, H2 blockers, H1 blockers) are contraindicated.

\(^b\) Carboplatin-based regimens are often used for patients with comorbidities or those who cannot tolerate cisplatin.

\(^c\) Contraindications for treatment with PD-1/PD-L1 inhibitors may include active or previously documented autoimmune disease and/or current use of immunosuppressive agents or presence of an oncogene, which would predict lack of benefit.

\(^d\) If progression on PD-1/PD-L1 inhibitor, switching to another PD-1/PD-L1 inhibitor is not routinely recommended.

\(^e\) Bevacizumab should be given until progression.

\(^f\) Any regimen with a high risk of thrombocytopenia and the potential risk of bleeding should be used with caution in combination with bevacizumab.

\(^g\) Criteria for treatment with bevacizumab: non-squamous NSCLC, and no recent history of hemoptysis. Bevacizumab should not be given as a single agent, unless as maintenance if initially used with chemotherapy.

**Note:** All recommendations are category 2A unless otherwise indicated.

**Clinical Trials:** NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
Initial Systemic Therapy Options

Squamous Cell Carcinoma (PS 0-1)

No contraindications to the addition of pembrolizumab

- Pembrolizumab/carboplatin/paclitaxel (category 1) (preferred)
- Pembrolizumab/carboplatin/albumin-bound paclitaxel (category 1) (preferred)
- Pembrolizumab/cisplatin/paclitaxel
- Pembrolizumab/cisplatin/albumin-bound paclitaxel

Contraindications to the addition of pembrolizumab

- Carboplatin/albumin-bound paclitaxel (category 1)
- Carboplatin/docetaxel
- Carboplatin/gemcitabine
- Carboplatin/paclitaxel
- Cisplatin/docetaxel
- Cisplatin/etoposide
- Cisplatin/gemcitabine
- Cisplatin/paclitaxel
- Gemcitabine/docetaxel
- Gemcitabine/vinorelbine
- Paclitaxel

Squamous Cell Carcinoma (PS 2)

- Albumin-bound paclitaxel
- Carboplatin/paclitaxel
- Carboplatin/docetaxel
- Carboplatin/etoposide
- Carboplatin/gemcitabine
- Carboplatin/paclitaxel
- Docetaxel
- Gemcitabine
- Gemcitabine/docetaxel
- Gemcitabine/vinorelbine
- Paclitaxel

---

\(a\) Albunim-bound paclitaxel may be substituted for either paclitaxel or docetaxel in patients who have experienced hypersensitivity reactions after receiving paclitaxel or docetaxel despite premedication, or for patients where the standard premedications (ie, dexamethasone, H2 blockers, H1 blockers) are contraindicated.

\(b\) Carboplatin-based regimens are often used for patients with comorbidities or those who cannot tolerate cisplatin.

\(c\) Contraindications for treatment with PD-1/PD-L1 inhibitors may include active or previously documented autoimmune disease and/or current use of immunosuppressive agents or presence of an oncogene, which would predict lack of benefit.

\(d\) If progression on PD-1/PD-L1 inhibitor, switching to another PD-1/PD-L1 inhibitor is not routinely recommended.

\(h\) Cisplatin/gemcitabine/nectumumab in the first-line setting and afatinib in the second-line setting are not used at NCCN Member Institutions for these indications related to the efficacy and safety of these agents compared to the efficacy and safety of other available agents.

---

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

<tr>
<td>T1</td>
<td>Tumor ≤3 cm in greatest dimension, surrounded by lung or visceral pleura, without bronchoscopic evidence of invasion more proximal than the lobar bronchus (i.e., not in the main bronchus)</td>
</tr>
<tr>
<td>T1mi</td>
<td>Minimally invasive adenocarcinoma: adenocarcinoma (≤3 cm in greatest dimension) with a predominantly lepidic pattern and ≤5 mm invasion in greatest dimension</td>
</tr>
<tr>
<td>T1a</td>
<td>Tumor ≤1 cm in greatest dimension. A superficial, spreading tumor of any size whose invasive component is limited to the bronchial wall and may extend proximal to the main bronchus also is classified as T1a, but these tumors are uncommon.</td>
</tr>
<tr>
<td>T1b</td>
<td>Tumor &gt;1 cm but ≤2 cm in greatest dimension</td>
</tr>
<tr>
<td>T1c</td>
<td>Tumor &gt;2 cm but ≤3 cm in greatest dimension</td>
</tr>
<tr>
<td>T2</td>
<td>Tumor &gt;3 cm but ≤5 cm or having any of the following features: (1) Involves the main bronchus, regardless of distance to the carina, but without involvement of the carina; (2) Invades visceral pleura (PL1 or PL2); (3) Associated with atelectasis or obstructive pneumonitis that extends to the hilar region, involving part or all of the lung</td>
</tr>
<tr>
<td>T2a</td>
<td>Tumor &gt;3 cm but ≤4 cm in greatest dimension</td>
</tr>
<tr>
<td>T2b</td>
<td>Tumor &gt;4 cm but ≤5 cm in greatest dimension</td>
</tr>
<tr>
<td>T3</td>
<td>Tumor &gt;5 cm but ≤7 cm in greatest dimension or directly invading any of the following: parietal pleura (PL3), chest wall (including superior sulcus tumors), phrenic nerve, parietal pericardium; or separate tumor nodule(s) in the same lobe as the primary</td>
</tr>
<tr>
<td>T4</td>
<td>Tumor &gt;7 cm or tumor of any size invading one or more of the following: diaphragm, mediastinum, heart, great vessels, trachea, recurrent laryngeal nerve, esophagus, vertebral body, carina; separate tumor nodule(s) in a ipsilateral lobe different from that of the primary</td>
</tr>
</tbody>
</table>

*aMost pleural (pericardial) effusions with lung cancer are a result of the tumor. In a few patients, however, multiple microscopic examinations of pleural (pericardial) fluid are negative for tumor, and the fluid is nonbloody and not an exudate. If these elements and clinical judgment dictate that the effusion is not related to the tumor, the effusion should be excluded as a staging descriptor.

### Table 1. Definitions for T, N, M (continued)

<table>

NCCN Guidelines Version 5.2019
Non-Small Cell Lung Cancer

Discussion

NCCN Categories of Evidence and Consensus

**Category 1:** Based upon high-level evidence, there is uniform NCCN consensus that the intervention is appropriate.

**Category 2A:** Based upon lower-level evidence, there is uniform NCCN consensus that the intervention is appropriate.

**Category 2B:** Based upon lower-level evidence, there is NCCN consensus that the intervention is appropriate.

**Category 3:** Based upon any level of evidence, there is major NCCN disagreement that the intervention is appropriate.

All recommendations are category 2A unless otherwise indicated.

Overview

Lung cancer is the leading cause of cancer death in the United States. In 2019, an estimated 228,150 new cases (116,440 in men and 111,710 in women) of lung and bronchial cancer will be diagnosed, and 142,670 deaths (76,650 in men and 66,020 in women) are estimated to occur because of the disease. Only 18% of all patients with lung cancer are alive 5 years or more after diagnosis. However, much progress has been made recently for lung cancer such as screening, minimally invasive techniques for diagnosis and treatment, and advances in radiation therapy (RT) including stereotactic ablative radiotherapy (SABR), targeted therapies, and immunotherapies. Patients with metastatic lung cancer who are eligible for targeted therapies or immunotherapies are now surviving longer. Common symptoms of lung cancer include cough, dyspnea, weight loss, and chest pain; patients with symptoms are more likely to have chronic obstructive pulmonary disease (COPD).

These NCCN Guidelines for Non-Small Cell Lung Cancer (NSCLC) were first published in 1996. Subsequently, the NCCN Guidelines have been updated at least once a year by the NCCN NSCLC Panel; there were 6 updates in 2018. The Summary of the Guidelines Updates describes the most recent revisions to the algorithms, which have been incorporated into this updated Discussion text (see the NCCN Guidelines for NSCLC and Summary in this Discussion). It is important to note that all recommendations are category 2A in the NCCN Guidelines unless otherwise indicated. Category 2A recommendations are based on lower level evidence (such as phase 2 trials) and uniform NCCN consensus (at least 85% of panel members) that the intervention is appropriate. By definition, the NCCN Guidelines cannot incorporate all possible clinical variations and are not intended to replace good clinical judgment or individualization of treatments.

Risk Factors

The primary risk factor for lung cancer is smoking tobacco, which accounts for most lung cancer-related deaths. Cigarette smoke contains many carcinogenic chemicals (eg, nitrosamines, benzo(a)pyrene diol epoxide). The risk for lung cancer increases with the number of packs of cigarettes smoked per day and with the number of years spent smoking (ie, pack-years of smoking history). Exposed nonsmokers also have an increased relative risk (RR = 1.24) of developing lung cancer from secondhand smoke; other studies have reported a modest risk (hazard ratio [HR], 1.05).
Other possible risk factors for lung cancer include disease history (e.g., COPD), cancer history, family history of lung cancer, and exposure to other carcinogens (see the NCCN Guidelines for Lung Cancer Screening, available at www.NCCN.org). The International Agency for Research on Cancer lists several agents known to cause lung cancer, including arsenic, chromium, asbestos, nickel, cadmium, beryllium, silica, and diesel fumes. Asbestos is a known carcinogen that increases the risk for lung cancer in people exposed to airborne fibers, especially in individuals who smoke. It is estimated that about 3% to 4% of lung cancers are caused by asbestos exposure. Asbestos also causes malignant pleural mesothelioma (see the NCCN Guidelines for Malignant Pleural Mesothelioma, available at www.NCCN.org). Radon gas, a radioactive gas that is produced by the decay of radium 226, also seems to cause lung cancer. It is not clear whether hormone replacement therapy (HRT) affects the risk for lung cancer in women. More than 20 studies have been published, but the results have been inconsistent. In a large randomized controlled study, no increase in the incidence of lung cancer was found among postmenopausal women treated with estrogen plus progestin HRT; however, the risk of death from NSCLC increased. In women who received estrogen alone, the incidence or risk of death from lung cancer did not increase.

Smoking Cessation

Approximately 85% to 90% of cases of lung cancer are caused by cigarette smoking. Active smoking and secondhand smoke both cause lung cancer. There is a causal relationship between active smoking and lung cancer and also between other cancers (e.g., esophageal, oral cavity, laryngeal, pharyngeal, bladder, pancreatic, gastric, kidney, ovarian cancer, colorectal, and cervical cancers) and other diseases and conditions. Smoking harms nearly every organ in the body; smokers have increased mortality compared with nonsmokers. Those who live with someone who smokes have an increased risk for lung cancer. Further complicating this problem, cigarettes also contain nicotine, which is a highly addictive substance.

Oncologists should encourage smoking cessation, especially in patients with cancer (see the NCCN Guidelines for Smoking Cessation, available at www.NCCN.org). The 5 A’s framework is a useful tool (that is, Ask, Advise, Assess, Assist, Arrange). It is in the best interest of patients to quit smoking. Persistent smoking is associated with second primary cancers, treatment complications, and decreased survival. Some surgeons will not operate on a current smoker, because active smoking may increase postoperative pulmonary complications. However, active smoking should not be used to exclude patients with early-stage lung cancer from surgical treatment that will prolong survival. Programs using behavioral counseling combined with medications that promote smoking cessation (approved by the FDA) can be very useful. The American Cancer Society (ACS) has a Guide to Quitting Smoking.

Agents that can be used to promote smoking cessation include nicotine replacement (e.g., gum, inhaler, lozenge, nasal spray, patch), bupropion sustained release, and varenicline. A study suggests that cytisine is more efficacious than nicotine replacement therapy, although more side effects were reported with cytisine such as nausea, vomiting, and sleep disorders. Studies have shown that varenicline is better than bupropion or nicotine patch for smoking cessation. The effectiveness of varenicline for preventing relapse has not been clearly established. The FDA has issued an alert for varenicline regarding neuropsychiatric symptoms. Varenicline has also been associated with visual disturbances, movement disorders, unconsciousness, and cardiovascular disorders; therefore, it is banned in truck and bus drivers, pilots, and air traffic controllers. Other side effects with varenicline include nausea,
abnormal dreams, insomnia, and headache.\textsuperscript{45,51,52} Bupropion may also be associated with similar serious neuropsychiatric symptoms. Nicotine replacement has fewer adverse effects than varenicline or bupropion.\textsuperscript{53} In spite of the potential adverse effects, it is probably more beneficial for motivated patients to use agents to promote smoking cessation.\textsuperscript{53}

**Lung Cancer Screening**

Lung cancer is the leading cause of cancer death worldwide in men, and late diagnosis is a major obstacle to improving lung cancer outcomes.\textsuperscript{1,54,55} Because localized cancer can be managed with curative intent and because the mortality rate in other solid tumors (eg, cervix, colon) seems to be decreased by screening and early detection, lung cancer is an appropriate candidate for a population-based screening approach.

The National Lung Screening Trial (NLST) (ACRIN Protocol A6654) was a randomized controlled study involving more than 53,000 current or former heavy smokers that assessed the risks and benefits of low-dose CT scans compared with chest radiographs for detecting lung cancer.\textsuperscript{56} Data from the NLST showed that screening individuals with high-risk factors using low-dose CT decreased the mortality rate from lung cancer by 20%.\textsuperscript{57} Individuals with high-risk factors were either current or former smokers with a 30 or more pack-year smoking history (former smokers had quit up to 15 years before enrollment), were 55 to 74 years of age, and had no evidence of lung cancer.\textsuperscript{56,58} The NCCN, ACS, U.S. Preventive Services Task Force (USPSTF), American College of Chest Physicians, European Society for Medical Oncology (ESMO), and other organizations recommend lung cancer screening using low-dose CT for select high-risk current and former smokers (see the NCCN Guidelines for Lung Cancer Screening, available at \url{www.NCCN.org}).\textsuperscript{59-62} Low-dose CT screening and follow-up are not a substitute for smoking cessation; patients should be offered smoking cessation counseling (see NCCN Guidelines for Smoking Cessation, available at \url{www.NCCN.org}).

**Classification and Prognostic Factors**

WHO divides lung cancer into 2 major classes based on its biology, therapy, and prognosis: NSCLC (discussed in these guidelines) and small cell lung cancer (SCLC) (see the NCCN Guidelines for Small Cell Lung Cancer, available at \url{www.NCCN.org}).\textsuperscript{63,64} NSCLC accounts for more than 80% of all lung cancer cases, and it includes 2 major types: 1) nonsquamous carcinoma (including adenocarcinoma, large-cell carcinoma, and other subtypes); and 2) squamous cell (epidermoid) carcinoma.\textsuperscript{3} Adenocarcinoma is the most common subtype of lung cancer seen in the United States and is also the most frequently occurring histology in nonsmokers. In 2011, an international panel revised the classification of lung adenocarcinoma (see the Pathologic Evaluation of Lung Cancer in this Discussion), which has been adopted by WHO.\textsuperscript{63-65} All NSCLC should be classified according to subtype using the WHO Guidelines.\textsuperscript{64} Recently, the NCCN NSCLC Panel extensively revised the pathology section (see Principles of Pathologic Review in the NCCN Guidelines for NSCLC and Pathologic Evaluation of Lung Cancer in this Discussion). Some of the recent changes include the addition of information about adenosquamous carcinomas, large cell carcinomas, and carcinoid tumors. Certain prognostic factors are predictive of survival in patients with NSCLC. Good prognostic factors include early-stage disease at diagnosis, good performance status (PS) (ECOG 0, 1), no significant weight loss (<5%), and female gender.\textsuperscript{66}

**Diagnostic Evaluation**

**Incidental Lung Nodules**

Lung cancer screening is recommended for early diagnosis in asymptomatic patients at high risk. Risk assessment is used to determine which individuals are at high risk for lung cancer and thus are candidates for screening with low-dose CT.\textsuperscript{67} Clinicians are referred to the NCCN Guidelines for Lung Cancer Screening for risk assessment criteria to
determine which patients are eligible for screening and for how to evaluate and follow up on low-dose CT screening findings. The NCCN Guidelines for Lung Cancer Screening were recently revised to harmonize with the LungRADs system developed by the American College of Radiology with the goal of decreasing the false-positive low-dose CT screening results reported in the NLST.

The diagnostic algorithm for pulmonary nodules in the NCCN Guidelines for NSCLC incorporates information from the NCCN Guidelines for Lung Cancer Screening. Recently, the NCCN NSCLC Panel revised the diagnostic algorithms for incidental solid and subsolid lung nodules detected on chest CT based on the updated Fleischner criteria (see the NCCN Guidelines for NSCLC). The cutoff thresholds were increased to 6 mm for a positive scan result. Note that the Fleischner Society Guidelines do not specify whether a CT with contrast is necessary for follow-up or whether a low-dose CT is sufficient. Low-dose CT is preferred unless contrast enhancement is needed for better diagnostic resolution.

Solid and subsolid nodules are the 2 main types of pulmonary nodules that may be seen on chest CT scans. The Fleischner Society has recommendations for patients with solid and subsolid nodules. Subsolid nodules include: 1) nonsolid nodules also known as ground-glass opacities (GGOs) or ground-glass nodules (GGNs); and 2) part-solid nodules, which contain both ground-glass and solid components.

Nonsolid nodules are mainly adenocarcinoma in situ (AIS) or minimally invasive adenocarcinoma (MIA), formerly known as bronchioloalveolar carcinoma (BAC) (see Adenocarcinoma in this Discussion); patients have 5-year disease-free survival of 100% if these nonsolid nodules are completely resected. Data suggest that many nonsolid nodules discovered incidentally on CT imaging will resolve and many of those that persist may not progress to clinically significant cancer. Solid and part-solid nodules are more likely to be invasive, faster-growing cancers, factors that are reflected in the increased suspicion and follow-up of these nodules (see the NCCN Guidelines for Lung Cancer Screening, available at www.NCCN.org).

All findings and factors for a patient need to be carefully evaluated in a multidisciplinary diagnostic team before establishing a diagnosis of lung cancer and before starting treatment. The NCCN Guidelines recommend biopsy or surgical excision for highly suspicious nodules seen on low-dose CT scans or further surveillance for nodules with a low suspicion of cancer depending on the type of nodule and a multidisciplinary evaluation of other patient factors (see the NCCN Guidelines for Lung Cancer Screening, available at www.NCCN.org). For patients having repeat scans, the most important radiologic factor is change or stability of a nodule when compared with a previous imaging study. False-positive results (eg, benign intrapulmonary lymph nodes, noncalcified granulomas) frequently occurred with low-dose CT when using the original cutoffs for nodule size deemed suspicious for malignancy from the NLST. The revised cutoff values for suspicious nodules recommended by the American College of Radiology and incorporated into the LungRADs system have been reported to decrease the false-positive rate from low-dose CT.

Larger Tumors

The NCCN Guidelines recommend that the diagnostic strategy should be individualized for each patient depending on the size and location of the tumor, the presence of mediastinal or distant disease, patient characteristics (eg, comorbidities), and local expertise. The diagnostic strategy needs to be decided in a multidisciplinary setting. Decisions regarding whether a biopsy (including what type of biopsy) or surgical excision is appropriate depend on several factors as outlined in the NSCLC algorithm (see Principles of Diagnostic Evaluation in the NCCN Guidelines for NSCLC). For example, a preoperative biopsy may be appropriate if an intraoperative diagnosis seems to be difficult or very risky.
Pathologic Evaluation of Lung Cancer

Pathologic evaluation is performed to classify the histologic subtype of the lung cancer, determine the extent of invasion, determine whether it is primary lung cancer or metastatic cancer, establish the cancer involvement status of the surgical margins (ie, positive or negative margins), and do molecular diagnostic studies to determine whether certain gene alterations are present (eg, epidermal growth factor receptor [EGFR] mutations) (see Principles of Pathologic Review in the NCCN Guidelines for NSCLC). Data show that targeted therapy is potentially very effective in patients with specific gene mutations or rearrangements; therefore, tissue needs to be conserved for molecular testing (see Principles of Molecular and Biomarker Analysis in the NCCN Guidelines for NSCLC).7,89-95

Preoperative evaluations include examination of the following: bronchial brushings, bronchial washings, sputum, FNA biopsy, core needle biopsy, endobronchial biopsy, and transbronchial biopsy.86,96 Minimally invasive techniques can be used to obtain specimens in patients with advanced unresectable NSCLC; however, diagnosis may be more difficult when using small biopsies and cytology.79 The mediastinal lymph nodes are systematically sampled to determine the staging and therapeutic options. Other lung diseases also need to be ruled out (eg, tuberculosis, sarcoidosis, coccidioidomycosis).99-101 Lobectomy or pneumonectomy specimens are evaluated intraoperatively to determine the surgical resection margin status, diagnose incidental nodules discovered at the time of surgery, or evaluate the regional lymph nodes.

Postoperative evaluation provides the pathology characteristics necessary for the classification of tumor type, staging, and prognostic factors. The surgical pathology report should include the WHO histologic classification for carcinomas of the lung.63,64,102 In 2011, the classification for lung adenocarcinoma was revised by an international panel, which has been

(such as a small and central lesion, where it is difficult to wedge or do intraoperative core needle biopsy). The preferred biopsy technique depends on the disease site and is described in the NSCLC algorithm (see Principles of Diagnostic Evaluation). For example, radial endobronchial ultrasound (EBUS; also known as endosonography), navigational bronchoscopy, or transthoracic needle aspiration (TTNA) are recommended for patients with suspected peripheral nodules.86

PET/CT imaging is useful before selecting a biopsy site, because it is better to biopsy the site that will confer the highest stage. For patients with suspected nodal disease, pathologic mediastinal lymph node evaluation is recommended with either noninvasive or invasive staging methods, including endoscopic ultrasound–guided fine-needle aspiration (EUS-FNA), EBUS–guided transbronchial needle aspiration (EBUS-TBNA), navigational bronchoscopy, or mediastinoscopy (see Mediastinal Lymph Node Evaluation in this Discussion and Principles of Diagnostic Evaluation in the NCCN Guidelines for NSCLC). Clinicians use both noninvasive and invasive methods when staging patients.87 EBUS provides access to nodal stations 2R/2L, 4R/4L, 7, 10R/10L, and other hilar nodal stations. EUS provides access to nodal stations 5, 7, 8, and 9.

If pathology results from biopsy or surgical excision indicate a diagnosis of NSCLC, then further evaluation and staging need to be done so that the patient’s health care team can determine the most appropriate and effective treatment plan (see Pathologic Evaluation of Lung Cancer and Staging in this Discussion and the NCCN Guidelines for NSCLC). Diagnosis, staging, and planned resection (eg, lobectomy) are ideally one operative procedure for patients with early-stage disease (see the Principles of Diagnostic Evaluation in the NCCN Guidelines for NSCLC). A preoperative or intraoperative tissue diagnosis of lung cancer should be established before doing a lobectomy.
Adopted by the WHO (see Adenocarcinoma in this Discussion). The revised classification recommends immunohistochemical (IHC) and molecular studies (see Principles of Pathologic Review in the NCCN Guidelines for NSCLC). In addition, the revised classification recommends that use of general categories (eg, non-small cell carcinoma [NSCC], NSCC not otherwise specified [NOS]) should be minimized, because more effective treatment can be selected when the histology is known.

Recently, the NCCN NSCLC Panel extensively revised the pathology section in the algorithm, including new information about adenosquamous carcinomas, large cell carcinomas, and carcinoid tumors (see Principles of Pathologic Review in the NCCN Guidelines for NSCLC). The purpose of the pathologic evaluation of NSCLC varies depending on whether the sample is 1) intended for initial diagnosis in a case of suspected NSCLC; 2) a definitive resection sample; or 3) obtained for molecular evaluation in the setting of an established NSCLC diagnosis. Further details are provided in the algorithm. All NSCLC should be classified according to subtype using the WHO Guidelines. Major subtypes of NSCLC include adenocarcinoma, squamous cell carcinoma, adenosquamous carcinoma, large cell carcinoma, carcinoid tumor, and less common subtypes that are not discussed here. Ideally, the subtype should be obtained. The general terms NSCC or NSCC NOS should be used infrequently and only when a more specific diagnosis cannot be obtained by morphology and/or special staining.

Adenocarcinomas include AIS, MIA, invasive adenocarcinomas, and invasive adenocarcinoma variants (see Adenocarcinoma in this Discussion and the NCCN Guidelines for NSCLC). Squamous cell carcinoma is a malignant epithelial tumor that 1) shows either keratinization and/or intercellular bridges; or 2) is an undifferentiated NSCC that demonstrates positivity for squamous cell carcinoma markers by IHC. Adenosquamous carcinomas are tumors with mixed adenocarcinoma and squamous cell carcinoma components; each component comprises at least 10% of the tumor. The presence of any adenocarcinoma component in a biopsy specimen that is otherwise squamous should trigger molecular testing. Large cell carcinomas are tumors lacking morphologic or IHC evidence of clear lineage, with negative or uninformative stains for squamous cell carcinoma and adenocarcinoma. The diagnosis of large cell carcinoma requires a thoroughly sampled resected tumor and cannot be made on non-resected or cytology specimens. Staining for large cell carcinomas should include mucin stain to look for occult glandular differentiation. Although carcinoid tumors are not treated like other types of NSCLC, they are staged in the same manner and are part of the differential diagnosis of pulmonary lesions. Care should be taken to properly distinguish typical carcinoid from atypical carcinoid by assessing for necrosis and using a morphologic mitotic count.

Adenocarcinoma

As previously mentioned, most lung carcinomas are adenocarcinomas. In 2011, the classification for lung adenocarcinoma was revised by an international panel and adopted by WHO. The revised classification recommends that use of general categories—NSCC and NSCC NOS—should be minimized, because more effective treatment can be selected when the specific subtype is known; IHC and molecular studies are also recommended (see Principles of Pathologic Review in the NCCN Guidelines for NSCLC).

The categories of BAC or mixed subtype adenocarcinoma are no longer used to classify adenocarcinoma. The categories for adenocarcinoma include: 1) AIS, which is a preinvasive, typically solitary lesion that is usually non-mucinous; 2) MIA, which is a solitary and discrete non-mucinous lesion with a maximum area of invasion no greater than 0.5
cm; and 3) invasive adenocarcinoma (see the NCCN Guidelines for NSCLC). Both AIS and MIA are associated with excellent survival if they are resected. The terms AIS, MIA, and large cell carcinoma should not be used for small samples because of challenges with complete assessment of the lesion.65

The international panel and the NCCN NSCLC Panel recommend that all patients with adenocarcinoma be tested for EGFR mutations; the NCCN NSCLC Panel also recommends that patients receive routine testing for anaplastic lymphoma kinase (ALK) gene rearrangements, ROS1 rearrangements, BRAF mutations, and programmed death (PD-1) receptor expression levels by IHC, because FDA-approved agents for lung cancer are available for these biomarkers. For the 2019 update (Version 1), the NCCN NSCLC Panel revised the recommendation for PD-L1 IHC testing to category 1 (from category 2A) in patients with metastatic NSCLC based on phase 3 randomized trial data.104 The panel also advises consideration of testing for other genetic alterations, such as NTRK gene fusions, RET rearrangements, MET genetic alterations, and ERBB2 (HER2) mutations, to identify rare oncogenic driver alterations for which effective therapy may be available (see Emerging Biomarkers to Identify Novel Therapies for Patients With Metastatic NSCLC in the NCCN Guidelines for NSCLC).105-107

Immunohistochemical Staining
Judicious use of IHC in small tissue samples is strongly recommended to conserve tumor tissue for molecular studies, especially in patients with advanced disease (see Principles of Pathologic Review in the NCCN Guidelines for NSCLC).98,108 Note that IHC analyses used to identify tumor type and lineage (eg, adenocarcinoma vs. squamous cell carcinoma) are distinct from IHC analyses used to determine whether patients are candidates for ALK inhibitor therapy or PD-1 ligand (PD-L1) inhibitor therapy. Before using IHC to determine histologic subtype, all material should be assessed morphologically, including routine staining approaches such as hematoxylin and eosin (H&E) histology (or relevant stains for cytology specimens), clinical findings, imaging studies, and the patient’s history. Cytology may be sufficient to distinguish adenocarcinomas from squamous cell carcinomas.109 If necessary, IHC should be used to distinguish adenocarcinoma, squamous cell carcinoma, metastatic malignancy, and primary pleural mesothelioma (particularly for pleural samplings). IHC is useful for poorly differentiated NSCLC in small biopsy and/or cytology specimens.65,110 Squamous cell carcinomas are often TTF-1 negative and p40 (or alternatively p63) positive, whereas adenocarcinomas are usually TTF-1 positive.65 These 2 markers may be sufficient to distinguish adenocarcinomas from squamous cell carcinomas.65,110 Other markers (eg, p40, Napsin A) may also be useful in distinguishing adenocarcinoma from squamous cell carcinoma.111,112 Napsin A positivity occurs in more than 80% of lung adenocarcinomas. In small biopsy specimens previously classified as NSCC NOS, a panel of TTF-1 (or alternatively Napsin A) and p40 (or alternatively p63) may be sufficient to refine the diagnosis to either adenocarcinoma or squamous cell carcinoma. Note that p63 can co-stain with TTF-1 or Napsin A in adenocarcinoma.

An appropriate panel of IHC stains should include those relevant for evaluation of metastatic carcinomas to the lung if the primary origin of the carcinoma is uncertain. It is appropriate to first perform a limited panel of IHC to evaluate for NSCLC and, if negative, then proceed to additional IHC for evaluation of possible metastasis from a distant site. TTF-1 is very important for distinguishing primary lung adenocarcinoma from metastatic adenocarcinoma, because most (70%–90%) non-mucinous primary adenocarcinomas are TTF-1 positive. TTF-1 is typically negative in squamous cell carcinoma.110 However, TTF-1 is also positive in tumors such as thyroid cancer and rarely in a few other organ systems.113 In addition, thyroglobulin and PAX8 are positive in tumors from patients with
thyroid cancer, while they are negative in lung cancer tumors. Immunomarkers that may be useful to assess for metastatic carcinoma to the lung include breast carcinoma (GCDFP-15, mammaglobin), renal cell carcinoma (PAX8), papillary serous carcinoma (PAX8, PAX2, ER), and adenocarcinomas of the gastrointestinal tract (CDX2) or prostate gland (NKX3.1). All typical and atypical carcinoid tumors are positive for chromogranin and synaptophysin, whereas SCLC is negative in 25% of cases.

Malignant pleural mesothelioma is a rare disease.\textsuperscript{114,115} The NCCN NSCLC Panel feels that malignant mesothelioma and lung adenocarcinoma can be distinguished using clinical impression, imaging, and a limited panel of immunomarkers (if needed) to preserve tissue for molecular testing. Commonly used immunostains sensitive and specific for adenocarcinoma include pCEA, Claudin4, TTF-1, and Napsin A (negative in mesothelioma). Other potentially useful markers include B72.3, Ber-EP4, MOC31, and CD15; however, these markers generally do not have the sensitivity and specificity of the commonly used markers. Immunostains sensitive and specific for mesothelioma include WT-1, calretinin, cytokeratin 5/6, and D2-40 (podoplanin antibody) (negative in adenocarcinoma).\textsuperscript{114-116} Broad epithelial markers such as keratin(s), as well as other lineage-specific markers, should be used when the differential diagnosis includes non-pulmonary and non-mesothelial lesions. Other markers can be useful in the differential diagnosis between mesothelioma and metastatic carcinoma to the lung (see \textit{Principles of Pathologic Review} in the NCCN Guidelines for NSCLC).

Although the cytologic diagnosis of NSCLC is generally reliable, it is more difficult to diagnose SCLC.\textsuperscript{86,110,117} Many patients with SCLC have characteristic CT and clinical findings (eg, massive lymphadenopathy, mediastinal invasion). Most SCLCs are immunoreactive for TTF-1; they are typically negative for CK34βE12 and p63.\textsuperscript{118,119} Many SCLCs also stain positively for markers of neuroendocrine differentiation, including chromogranin and synaptophysin. IHC should be used to confirm neuroendocrine differentiation only when appropriate morphologic features—speckled chromatin pattern, nuclear molding, and peripheral palisading—are present. NCAM (CD56), chromogranin, and synaptophysin are used to identify neuroendocrine tumors if morphologic suspicion of neuroendocrine differentiation exists. One positive marker is sufficient if the staining is not ambiguous in more than 10% of the tumor cells.

**Staging**

A revised edition of the AJCC Cancer Staging Manual (8th edition) was published in late 2016 and is effective for all cancer cases recorded on or after January 1, 2018.\textsuperscript{120} The NCCN Guidelines used the AJCC (7th edition) staging system for lung cancer until January 1, 2018.\textsuperscript{121} The definitions for TNM and the stage grouping for the eighth edition are summarized in Tables 1 and 2 of the staging tables (see Definitions for \textit{T,N,M} and \textit{Staging} in the NCCN Guidelines for NSCLC). The descriptors of the TNM classification scheme are summarized in Table 3 of the staging tables, which shows the differences between the seventh and eighth editions (see \textit{Staging}).\textsuperscript{122} The lung cancer staging system was revised by the International Association for the Study of Lung Cancer (IASLC)\textsuperscript{123-125} and was adopted by the AJCC.\textsuperscript{126,127} Early-stage disease is stages I and II with negative nodes (N0), whereas locally advanced disease is stages II and III with positive nodes (N+);\textsuperscript{128} advanced or metastatic disease is stage IV. Pathologic staging uses both clinical staging information (which is noninvasive and includes medical history, physical examination, and imaging) and other invasive staging procedures (eg, thoracotomy, examination of lymph nodes using mediastinoscopy).\textsuperscript{121}

From 2008 to 2014, the overall 5-year relative survival rate for NSCLC was 22.7% in the United States.\textsuperscript{3} Of NSCLC and bronchial cancer cases,
19% were diagnosed while the cancer was still confined to the primary site; 24% were diagnosed after the cancer had spread to regional lymph nodes or directly beyond the primary site; 55% were diagnosed after the cancer had already metastasized; and for the remaining 2% the staging information was unknown. The corresponding 5-year relative survival rates were 60.1% for localized, 33.4% for regional, 5.5% for distant, and 13.8% for unstaged.3

Five-year survival after lobectomy for pathologic stage I NSCLC ranges from 45% to 65%, depending on whether the patient has stage 1A or 1B disease and on the location of the tumor.129 Another study in patients with stage I disease (n = 19,702) found that 82% had surgical resection and their 5-year overall survival was 54%; for untreated stage I NSCLC, 5-year overall survival was only 6%.130 Of patients with stage I disease who refused surgery (although it was recommended), 78% died of lung cancer within 5 years.

Predictive and Prognostic Biomarkers

Several biomarkers have emerged as predictive and prognostic markers for NSCLC. A predictive biomarker is indicative of therapeutic efficacy, because there is an interaction between the biomarker and therapy on patient outcome. A prognostic biomarker is indicative of patient survival independent of the treatment received, because the biomarker is an indicator of the innate tumor behavior (see KRAS Mutations at the end of this section). A section on biomarkers was recently added to the algorithm and the content was revised for the 2019 update (Version 1) (see Principles of Molecular and Biomarker Analysis in the NCCN Guidelines for NSCLC). For example, new information about plasma cell-free/circulating tumor DNA testing (so-called “liquid biopsy”) for genetic alterations was added to the section on biomarkers. Briefly, the panel feels that cell-free/circulating tumor DNA testing should not be used in lieu of tissue diagnosis. Standards and guidelines for cell-free DNA (cfDNA)/circulating tumor DNA testing for genetic alterations have not been established, there is up to a 30% false-negative rate, and alterations can be detected that are not related to the tumor (eg, clonal hematopoiesis of indeterminate potential [CHIP]).131,132 For example, an IDH1 mutation identified by cfDNA testing is likely unrelated to NSCLC, given exceptionally low incidence, and is more likely to represent CHIP. Rare examples of CHIP with KRAS mutations have been described, suggesting caution in the interpretation of cfDNA findings.133 In addition, CHIP can be identified following prior chemotherapy or radiotherapy, further confounding interpretation of alterations such as in TP53.134 However, cfDNA testing can be used in specific circumstances if 1) the patient is not medically fit for invasive tissue sampling, or 2) there is insufficient tissue for molecular analysis and follow-up tissue-based analysis will be done if an oncogenic driver is not identified. Given the previous caveats, careful consideration is required to determine whether cfDNA findings reflect a true driver mutation or an unrelated finding.

Predictive biomarkers include the ALK fusion oncogene (fusion between ALK and other genes [eg, echinoderm microtubule-associated protein-like 4]), ROS1 gene rearrangements, sensitizing EGFR gene mutations, BRAF V600E point mutations, and PD-L1 expression (see Principles of Molecular and Biomarker Analysis in the NCCN Guidelines for NSCLC). Emerging predictive biomarkers include ERBB2 (also known as HER2) mutations, RET gene rearrangements, high-level MET amplifications or MET exon 14 skipping mutations (METex14), and tumor mutational burden (TMB) (see Emerging Biomarkers to Identify Novel Therapies for Patients With Metastatic NSCLC in the NCCN Guidelines for NSCLC). The presence of EGFR exon 19 deletions or exon 21 L858R mutations is predictive of treatment benefit from EGFR tyrosine kinase inhibitor (EGFR TKI) therapy (eg, erlotinib); therefore, these mutations are referred to as sensitizing EGFR mutations (see EGFR Mutations in this Discussion).135,136 The presence of EGFR exon 19 deletions (LREA) or
exon 21 L858R mutations does not appear to be prognostic of survival for patients with NSCLC, independent of therapy.\textsuperscript{137}

**ALK** fusion oncogenes (ie, **ALK** gene rearrangements) and **ROS1** rearrangements are predictive biomarkers that have been identified in a small subset of patients with NSCLC; both predict for benefit from targeted therapy such as crizotinib or ceritinib (see **ALK Gene Rearrangements** and **ROS1 Rearrangements** in the NCCN Guidelines for NSCLC). Other gene rearrangements (ie, gene fusions) have recently been identified (such as **RET**) that are susceptible to targeted therapies, particularly therapies currently under investigation in clinical trials (see **Emerging Biomarkers to Identify Novel Therapies for Patients With Metastatic NSCLC** in the NCCN Guidelines for NSCLC).\textsuperscript{138-143}

Testing for **ALK** gene rearrangements and **EGFR** gene mutations is recommended (category 1 for both) in the NSCLC algorithm for patients with metastatic nonsquamous NSCLC or NSCLC NOS so that patients with these genetic abnormalities can receive effective treatment with targeted agents (see **Targeted Therapies** in this Discussion and the NCCN Guidelines for NSCLC).\textsuperscript{144-148} Testing for **ROS1** rearrangements and **BRAF** mutations (both are category 2A) is also recommended in the NCCN Guidelines for nonsquamous NSCLC or NSCLC NOS. Although rare, patients with **ALK** rearrangements or **EGFR** mutations can have mixed squamous cell histology.\textsuperscript{149,150} Therefore, testing for **ALK** rearrangements and **EGFR** mutations can be considered in select patients with metastatic squamous cell carcinoma if they are never smokers, small biopsy specimens were used for testing, or mixed histology was reported. Data suggest that **EGFR** mutations occur in patients with adenosquamous carcinoma at a rate similar to adenocarcinoma, which is harder to discriminate from squamous cell carcinoma in small specimens.\textsuperscript{149} Thus, testing for **EGFR** mutations and **ALK** rearrangements is recommended in mixed squamous cell lung specimens that contain an adenocarcinoma component, such as adenosquamous NSCLC or in samples in which an adenocarcinoma component cannot be excluded.\textsuperscript{146} The incidence of **EGFR** mutations is very low in patients with pure squamous cell histology (<4%).\textsuperscript{151} Testing for **ROS1** rearrangements or **BRAF** mutations is also recommended (category 2A) in patients with squamous cell carcinoma who have small biopsy specimens or mixed histology. **EGFR**, **KRAS**, **ROS1**, and **ALK** genetic alterations do not usually overlap; thus, testing for **KRAS** mutations may identify patients who will not benefit from further molecular testing.\textsuperscript{138,152,153} **BRAF** mutations typically do not overlap with **EGFR** mutations or **ALK** rearrangements.\textsuperscript{154,155} For patients with metastatic nonsquamous NSCLC, the NCCN NSCLC Panel currently recommends that a minimum of the following biomarkers should be tested, including **EGFR** mutations, **BRAF** mutations, **ALK** rearrangements, **ROS1** rearrangements, and PD-L1 expression levels. This list of recommended biomarkers may be revised as new oncogenic driver alterations are identified and new agents are approved. Patients with NSCLC may have other genetic alterations (see **Emerging Biomarkers to Identify Novel Therapies for Patients With Metastatic NSCLC** in the NCCN Guidelines for NSCLC).\textsuperscript{90,156,157} The NCCN Guidelines do not endorse specific testing modalities or techniques for biomarker tests.\textsuperscript{158} Biomarker testing should be done at properly accredited laboratories (minimum of Clinical Laboratory Improvement Amendments [CLIA] accreditation) (see **Principles of Molecular and Biomarker Analysis** in the NCCN Guidelines for NSCLC).

Other driver mutations and gene rearrangements (ie, driver events) are being identified such as **RET** gene rearrangements, high-level **MET** amplification or **MET** exon 14 mutations, **ERBB2** mutations, and TMB.\textsuperscript{138,139,141,143,154,159-169} For the 2019 update (Version 1), the NCCN NSCLC Panel added TMB as a new emerging biomarker that may be
helpful for identifying patients with metastatic NSCLC who are eligible for first-line therapy with nivolumab with or without ipilimumab (see Nivolumab in this Discussion). However, there is no consensus on how to measure TMB. Targeted agents are available for patients with NSCLC who have these other genetic alterations, although they are FDA approved for other indications (see Emerging Biomarkers to Identify Novel Therapies for Patients With Metastatic NSCLC in the NCCN Guidelines for NSCLC). Thus, the NCCN NSCLC Panel strongly advises broader molecular profiling to identify rare driver mutations to ensure that patients receive the most appropriate treatment; patients may be eligible for clinical trials for some of these targeted agents. Several online resources are available that describe NSCLC driver events such as My Cancer Genome.

The KRAS oncogene is a prognostic biomarker. The presence of KRAS mutations is prognostic of poor survival for patients with NSCLC when compared to the absence of KRAS mutations, independent of therapy (see KRAS Mutations in this Discussion). KRAS mutations are also predictive of lack of benefit from EGFR TKI therapy. EGFR, KRAS, ROS1, and ALK genetic alterations do not usually overlap. BRAF mutations typically do not overlap with EGFR mutations or ALK rearrangements. EGFR TKI therapy is not effective in patients with KRAS mutations, BRAF V600E mutations, ALK gene rearrangements, or ROS1 rearrangements.

Molecular Testing for Biomarkers

Molecular testing is used to test for genomic alterations associated with oncogenic driver events if targeted therapies are available; these genomic alterations (also known as biomarkers) include mutations and gene rearrangements. The various molecular testing methods that may be used to assess for the different biomarkers are described in the algorithm (see Principles of Molecular and Biomarker Analysis in the NCCN Guidelines for NSCLC). Broad molecular profiling systems may be used to simultaneously test for multiple biomarkers.

Next-generation sequencing (NGS) (also known as massively parallel sequencing) is a type of broad molecular profiling system that can detect panels of mutations and gene rearrangements if the NGS platforms have been designed and validated to detect these genetic alterations. It is important to recognize that NGS requires quality control as much as any other diagnostic technique; because it is primer dependent, the panel of genes and abnormalities detected with NGS will vary depending on the design of the NGS platform. For example, some NGS platforms can detect both mutations and gene rearrangements, as well as copy number variation, but they are not uniformly present in all NGS assays being conducted either commercially or in institutional laboratories.

Other mutation screening assays are available for detecting multiple biomarkers simultaneously—such as Sequenom's MassARRAY® system and SNAPSHOT® Multiplex System—which can detect more than 50 point mutations; NGS platforms can detect even more biomarkers. However, these multiplex polymerase chain reaction (PCR) systems do not typically detect gene rearrangements. ROS1 and ALK gene rearrangements can be detected using fluorescence in situ hybridization (FISH), NGS, and other methods (see ALK Gene Rearrangements and ROS1 Rearrangements in this Discussion and Principles of Molecular and Biomarker Analysis in the NCCN Guidelines for NSCLC).

To minimize tissue use and potential wastage, the NCCN NSCLC Panel recommends that biomarker testing be done as part of broad molecular profiling using a validated test(s) that assesses a minimum of the following potential genetic alterations: EGFR mutations, BRAF mutations, ALK rearrangements, and ROS1 rearrangements. Both FDA and laboratory-developed test platforms are available that address the need to evaluate these and other analytes. Broad molecular profiling is
also recommended to identify rare driver mutations for which effective therapy may be available, such as neurotrophic receptor tyrosine kinase (NTRK) gene fusions, high-level MET amplification, MET exon 14 skipping mutation, RET rearrangements, ERBB2 (HER2) mutations, and TMB. Although clinicopathologic features—such as smoking status, ethnicity, and histology—are associated with specific genetic alterations (eg, EGFR mutations), these features should not be used to select patients for testing.

**EGFR Mutations**

In patients with NSCLC, the most commonly found EGFR gene mutations are deletions in exon 19 (Exon19del [with conserved deletion of the LREA sequence] in 45% of patients with EGFR mutations) and a point mutation in exon 21 (L858R in 40%). Both mutations result in activation of the tyrosine kinase domain, and both are associated with sensitivity to the small molecule EGFR TKIs, such as erlotinib, gefitinib, afatinib, osimertinib, and dacomitinib (see **Targeted Therapies** in this Discussion).189 Thus, these mutations are referred to as sensitizing EGFR mutations. Other less common mutations (10%) that are also sensitive to EGFR TKIs include exon 19 insertions, p.L861Q, p.G719X, and p.S768I (see **Principles of Molecular and Biomarker Analysis** in the NCCN Guidelines for NSCLC).190,191 Data suggest that patients harboring tumors without sensitizing EGFR mutations should not be treated with EGFR TKIs in any line of therapy. These sensitizing EGFR mutations are found in approximately 10% of Caucasian patients with NSCLC and up to 50% of Asian patients.192

Most patients with sensitizing EGFR mutations are nonsmokers or former light smokers with adenocarcinoma histology. However, smoking status, ethnicity, and histology should not be used in selecting patients for testing. EGFR mutation testing is not usually recommended in patients with pure squamous cell carcinoma unless they are a former light or never-smoker, if only a small biopsy specimen (ie, not a surgical resection) was used to assess histology, or if the histology is mixed.149 Data suggest that EGFR mutations can occur in patients with adenosquamous carcinoma, which is harder to discriminate from squamous cell carcinoma in small specimens.149

The predictive effects of the drug-sensitive EGFR mutations are well defined. Patients with these mutations have a significantly better response to erlotinib, gefitinib, afatinib, osimertinib, or dacomitinib.189 Non-responsiveness to EGFR TKI therapy is associated with KRAS and BRAF mutations and ALK or ROS1 gene rearrangements. Patients with EGFR exon 20 insertion mutations are usually resistant to TKIs, although there are rare exceptions (see **Principles of Molecular and Biomarker Analysis** in the NCCN Guidelines for NSCLC).193-197 EGFR p.Thr790Met (T790M) is a mutation associated with acquired resistance to EGFR TKI therapy and has been reported in about 60% of patients with disease progression after initial response to erlotinib, gefitinib, or afatinib.185,198-204 Most patients with sensitizing EGFR mutations become resistant to erlotinib, gefitinib, or afatinib; progression-free survival (PFS) is about 9.7 to 13 months.199,205-208 Studies suggest T790M may also occur in patients who have not previously received erlotinib, gefitinib, or afatinib, although this is a rare event.209 Genetic counseling is recommended for patients with pre-treatment p.T790M, because this suggests the possibility of germline mutation and is associated with predisposition to familial lung cancer.210,211 Osimertinib is recommended (category 1) as second-line and beyond (subsequent) therapy for patients with EGFR T790M who have progressed on erlotinib, gefitinib, afatinib, or dacomitinib (see **Osimertinib in this Discussion**).208,212 For the 2019 update (Version 1), the NCCN NSCLC Panel voted that osimertinib is a preferred first-line therapy option (category 1) regardless of pre-treatment T790M status. Acquired resistance may also be associated with histologic transformation from NSCLC to SCLC and with epithelial to mesenchymal transition.213-215
Acquired resistance can also be mediated by other molecular events, such as acquisition of ALK rearrangement, MET, or ERBB2 amplification.216

DNA mutational analysis is the preferred method to assess for EGFR status; IHC is not recommended for detecting EGFR mutations.217-220 Real-time PCR, Sanger sequencing (paired with tumor enrichment), and NGS are the most commonly used methods to assess EGFR mutation status (see Principles of Molecular and Biomarker Analysis in the NCCN Guidelines for NSCLC).148,217 Direct sequencing of DNA corresponding to exons 18 to 21 (or just testing for exons 19 and 21) is a reasonable approach; however, more sensitive methods are available.192,219,221-223 Mutation screening assays using multiplex PCR (eg, Sequenom's MassARRAY® system, SNaPshot® Multiplex System) can simultaneously detect more than 50 point mutations.186 NGS can also be used to detect EGFR mutations.186

The predictive effects of the drug-sensitive EGFR mutations—Exon19del (LREA deletion) and L858R—are well defined. Patients with these mutations have a significantly better response to erlotinib, gefitinib, afatinib, osimertinib, or dacomitinib.189 Data show that EGFR TKI therapy should be used as first-line systemic therapy in patients with advanced NSCLC and sensitizing EGFR mutations documented before first-line therapy (see Targeted Therapies in this Discussion).206,224-228 PFS is improved with use of EGFR TKI in patients with sensitizing EGFR mutations when compared with cytotoxic systemic therapy, although overall survival is not statistically different.206,207,224 Patients receiving erlotinib have fewer treatment-related severe side effects and deaths when compared with those receiving chemotherapy.206,229 A phase 4 trial showed that gefitinib is safe and effective in patients with sensitizing EGFR mutations.145

Based on these data and the FDA approvals, erlotinib and gefitinib are recommended (category 1) as first-line systemic therapy in patients with sensitizing EGFR mutations including the less common mutations.145,206 In a phase 3 randomized trial, patients receiving afatinib had decreased cough, decreased dyspnea, and improved health-related quality of life when compared with those receiving cisplatin/pemetrexed.229 Based on these data and the FDA approval, afatinib is also recommended (category 1) as first-line systemic therapy in patients with sensitizing EGFR mutations.224 Afatinib was potentially associated with 4 treatment-related deaths, whereas there were none in the chemotherapy group.224 A combined analysis (LUX 3 and LUX 6) reported a survival advantage in patients with exon 19 deletions who received afatinib when compared with chemotherapy.230

**BRAF V600E Mutations**

BRAF (v-Raf murine sarcoma viral oncogene homolog B) is a serine/threonine kinase that is part of the MAP/ERK signaling pathway. **BRAF V600E** is the most common of the BRAF point mutations when considered across all tumor types; it occurs in 1% to 2% of patients with lung adenocarcinoma.154,231 Although other BRAF mutations occur in patients with NSCLC at a rate approximately equal to p.V600E (unlike many other tumor types), specific targeted therapy is not available for these other mutations. Patients with BRAF V600E mutations are typically current or former smokers in contrast to those with EGFR mutations or ALK rearrangements who are typically nonsmokers.167 Mutations in BRAF typically do not overlap with EGFR mutations, ALK rearrangements, or ROS1 rearrangements.154,155 Testing for BRAF mutations is recommended (category 2A) in patients with metastatic nonsquamous NSCLC and may be considered in patients with squamous cell carcinoma NSCLC (category 2A) if small biopsy specimens were used to assess histology or mixed histology was reported.154,155 Real-time PCR, Sanger sequencing, and NGS are the most commonly used methods to assess for BRAF mutations.
(see *Principles of Molecular and Biomarker Analysis* in the NCCN Guidelines for NSCLC).

The NCCN NSCLC Panel recommends testing for *BRAF* mutations based on data showing the efficacy of dabrafenib/trametinib for patients with *BRAF* V600E mutations and on the FDA approval (see *Dabrafenib and Trametinib* in this Discussion). Dabrafenib/trametinib or doublet chemotherapy regimens also used for initial cytotoxic therapy (eg, carboplatin/pemetrexed for nonsquamous NSCLC) are recommended for patients with *BRAF* V600E mutations. Single-agent therapy with dabrafenib or vemurafenib is recommended if combination therapy with dabrafenib/trametinib is not tolerated.

**ALK Gene Rearrangements**

About 5% of patients with NSCLC have *ALK* gene rearrangements. Patients with *ALK* rearrangements are resistant to EGFR TKIs but have similar clinical characteristics to those with *EGFR* mutations (ie, adenocarcinoma histology, light or never-smokers). *ALK* rearrangements are not routinely found in patients with squamous cell carcinoma. Patients with *ALK* gene rearrangements can have mixed squamous cell histology. It can be challenging to accurately determine histology in small biopsy specimens; thus, patients may have mixed squamous cell histology (or squamous components) instead of pure squamous cell.

The NCCN NSCLC Panel recommends testing for *ALK* rearrangements in patients with metastatic nonsquamous NSCLC; testing can be considered if small biopsy specimens were used to assess histology, mixed histology was reported, or patients are light or never-smokers. The different testing methods for *ALK* rearrangements are described in the algorithm (see *Principles of Molecular and Biomarker Analysis* in the NCCN Guidelines for NSCLC). A molecular diagnostic test (using FISH) has been approved by the FDA for detecting *ALK* rearrangements. Rapid prescreening with IHC to assess for *ALK* rearrangements can be done. An IHC assay for *ALK* rearrangements has also been approved by the FDA. NGS can also be used to assess whether *ALK* rearrangements are present, if the platform has been appropriately designed and validated to detect *ALK* rearrangements.

**First-Line Therapy**

Alectinib is an oral TKI that inhibits *ALK* and *RET* rearrangements but not *MET* or *ROS1* rearrangements. A phase 3 randomized trial (ALEX) assessed first-line therapy with alectinib versus crizotinib in 303 patients with *ALK*-positive advanced NSCLC, including those with asymptomatic central nervous system (CNS) disease. Disease progression or death occurred in fewer patients receiving alectinib (41% [62/152]; median follow-up of 18.6 months) when compared with crizotinib (68% [102/151]; median follow-up of 17.6 months). The HR was 0.47 (95% CI, 0.34–0.65; *P* < .001) for disease progression or death. PFS was significantly increased with alectinib (68.4% [95% CI, 61.0%–75.9%] versus crizotinib (48.7% [95% CI, 40.4%–56.9%]. The median PFS was not reached for alectinib (95% CI, 17.7 months–not reached) when compared with crizotinib at 11.1 months (95% CI, 9.1–13.1). Fewer patients receiving alectinib had CNS progression (12% [18/152]) versus crizotinib (45% [68/151]). Response rates were 83% (126/152) in the alectinib group versus 75% (114/151) in the crizotinib group (*P* = .09). Patients receiving alectinib had fewer grade 3 to 5 adverse events when compared with crizotinib (41% [63/152] vs. 50% [75/151], respectively) even though patients received alectinib for a longer duration than crizotinib (median, 17.9 vs. 10.7 months). Fewer deaths were reported in the alectinib arm (3.3% [5/152]) compared with the crizotinib arm (4.6% [7/151]); 2 treatment-related deaths were reported in the crizotinib arm and none were reported in the alectinib arm.
Another phase 3 randomized trial (J-ALEX) assessed first-line therapy with alectinib versus crizotinib in 207 Japanese patients with ALK-positive advanced NSCLC. The data showed that median PFS had not yet been reached with alectinib (95% CI, 20.3 months—not reached) versus 10.2 months (95% CI, 8.2–12.0) with crizotinib (HR, 0.34 [99.7% CI, 0.17–0.71], stratified log-rank \( P < .0001 \)). Grade 3 or 4 adverse events were less frequent with alectinib (26% [27/103]) when compared with crizotinib (52% [54/104]); adverse events did not lead to death in either group. Fewer patients stopped taking alectinib (9%) because of an adverse event when compared with crizotinib (20%). The NCCN NSCLC Panel recommends alectinib as a preferred first-line treatment (category 1) for patients with ALK-positive metastatic NSCLC based on these clinical trials. Three other ALK inhibitors, crizotinib, brigatinib, and ceritinib, are also recommended (category 1 for all) by the NCCN NSCLC Panel as first-line therapy for patients with ALK rearrangements based on clinical trial data and FDA approvals for crizotinib and ceritinib (see Brigatinib, Crizotinib, and Ceritinib in this Discussion).

**Subsequent Therapy**

Patients typically progress after first-line therapy with alectinib, brigatinib, crizotinib, or ceritinib; subsequent therapy recommendations are described in the algorithm [see Second-Line and Beyond (Subsequent) Systemic Therapy in this Discussion and the NCCN Guidelines for NSCLC]. The phrase *subsequent* therapy was recently substituted for the terms *second-line or beyond* systemic therapy, because the line of therapy may vary depending on previous treatment with targeted agents.

Lorlatinib is a third-generation TKI that targets ALK and ROS1 rearrangements; data show it is effective in select patients who have progressed after treatment with ALK inhibitors (see Lorlatinib in this Discussion). For the 2019 update (Version 2), the NCCN NSCLC Panel now recommends lorlatinib (category 2A) as a subsequent therapy option for select patients with ALK-positive NSCLC who have progressed after treatment with ALK inhibitors. For patients who progress on first-line crizotinib, subsequent treatment for ALK-positive NSCLC includes alectinib, brigatinib, or ceritinib (if not previously given) (see Ceritinib, Alectinib, and Brigatinib in this Discussion and the NCCN Guidelines for NSCLC). For patients who progress on first-line alectinib, brigatinib, or ceritinib, subsequent treatment for ALK-positive NSCLC includes lorlatinib or the initial systemic therapy regimens that are used for first-line treatment of NSCLC (eg, carboplatin/paclitaxel) depending on the type of progression. Continuing alectinib, brigatinib, crizotinib, or ceritinib with or without local therapy (eg, SABR, stereotactic radiosurgery [SRS], or surgery) may also be appropriate for select patients who progress on these agents depending on the type of progression [see Second-Line and Beyond (Subsequent) Systemic Therapy in this Discussion]. For patients who progress on second-line alectinib, brigatinib, or ceritinib, after initially receiving crizotinib, subsequent treatment for ALK-positive NSCLC includes lorlatinib or the initial systemic therapy regimens that are used for first-line treatment of NSCLC (eg, carboplatin/paclitaxel). For the 2019 update (Version 2), the NCCN NSCLC Panel also recommends lorlatinib (category 2A) as a subsequent therapy option for select patients with ROS1-positive NSCLC who have progressed after treatment with crizotinib or ceritinib.

**ALK or ROS1** rearrangements and sensitizing EGFR mutations are generally mutually exclusive. Thus, EGFR TKI therapy is not recommended as subsequent therapy in patients with ALK or ROS1 rearrangements who relapse on alectinib, brigatinib, crizotinib, ceritinib, or lorlatinib (see ALK Positive: Subsequent Therapy in the NCCN Guidelines for NSCLC). Likewise, crizotinib, ceritinib, alectinib, brigatinib, or lorlatinib are not recommended for patients with sensitizing EGFR mutations who relapse on EGFR TKI therapy.
ROS1 Rearrangements

Although ROS proto-oncogene 1 (ROS1) is a distinct receptor tyrosine kinase, it is very similar to ALK and members of the insulin receptor family (see Principles of Molecular and Biomarker Analysis in the NCCN Guidelines for NSCLC).\textsuperscript{139,256} It is estimated that ROS1 gene rearrangements occur in about 1% to 2% of patients with NSCLC; they occur more frequently in those who are negative for EGFR mutations, KRAS mutations, and ALK gene rearrangements (also known as triple negative).\textsuperscript{105,139,141,179} Crizotinib is very effective for patients with ROS1 rearrangements with response rates of about 70% to 80% including complete responses.\textsuperscript{138,139,257} A recent phase 2 trial assessed crizotinib in East Asian patients (n=127) with ROS1-positive advanced NSCLC who had received 3 or fewer lines of therapy. The overall response rate was 72% (95% CI, 63%–79%) with 17 complete responses; the median duration of response was 19.7 months (95% CI, 14.1–not reached). The median PFS was 15.9 months (95% CI, 12.9–24.0).\textsuperscript{257} In 50 patients, crizotinib yielded a response rate of 66% (95% CI, 51%–79%); the median duration of response was 18 months.\textsuperscript{139,258} The FDA has approved crizotinib for patients with ROS1 rearrangements.\textsuperscript{258}

The NCCN NSCLC Panel recommends crizotinib and ceritinib (both are category 2A) as first-line therapy for patients with ROS1 rearrangements based on trial data; however, the panel voted that crizotinib is the preferred agent because crizotinib is better tolerated when compared with ceritinib and because crizotinib has been approved by the FDA for this indication (see Crizotinib and Ceritinib in this Discussion). For the 2019 update (Version 1), the NCCN NSCLC Panel revised the ROS1 algorithm to include recommendations for patients discovered to have ROS1 rearrangements during first-line chemotherapy; planned chemotherapy may be either completed or interrupted followed by crizotinib or ceritinib.

The NCCN NSCLC Panel recommends ROS1 testing in patients with metastatic nonsquamous NSCLC based on data showing the efficacy of crizotinib and ceritinib for patients with ROS1 rearrangements (see Principles of Molecular and Biomarker Analysis in the NCCN Guidelines for NSCLC).\textsuperscript{138,139,258} ROS1 testing can be considered in patients with metastatic squamous cell carcinoma NSCLC if small biopsy specimens were used to assess histology or mixed histology was reported. Similar to testing for ALK rearrangements, testing for ROS1 rearrangements is also done using FISH.\textsuperscript{141,233,259-261} NGS can also be used to assess whether ROS1 rearrangements are present, if the platform has been appropriately designed and validated to detect ROS1 rearrangements.\textsuperscript{139} Because a companion diagnostic test has not been approved for ROS1 rearrangements, clinicians should use an appropriately validated test to detect ROS1 rearrangements.\textsuperscript{258} Alectinib, brigatinib, and ceritinib are not recommended in patients with ROS1 rearrangements whose disease becomes resistant to crizotinib.\textsuperscript{139} Studies are ongoing regarding new agents for patients with ROS1 rearrangements whose disease becomes resistant to crizotinib.\textsuperscript{262-265} For the 2019 update (Version 2), the NCCN NSCLC Panel now recommends lorlatinib (category 2A) as a subsequent therapy option for select patients with ROS1-positive NSCLC who have progressed after treatment with crizotinib or ceritinib (see Lorlatinib in this Discussion). Initial systemic therapy options that are used for adenocarcinoma or squamous cell carcinoma are also an option in this setting (eg, carboplatin/paclitaxel).

NTRK Gene Fusions

A diverse range of solid tumors in children and adults may be caused by NTRK gene fusions (eg, NTRK1, NTRK2, NTRK3). NTRK gene fusions encode tropomyosin receptor kinase (TRK) fusion proteins (eg, TRKA, TRKB, TRKC) that act as oncogenic drivers for solid tumors including lung, salivary gland, thyroid, and sarcoma.\textsuperscript{266,267} It is estimated that NTRK fusions occur in 0.2% of patients with NSCLC and do not typically overlap...
with other oncogenic drivers such as EGFR, ALK, or ROS1. Various methods can be used to detect NTRK gene fusions, including FISH, IHC, NGS, and PCR assays. In a recent clinical trial, NTRK gene fusions were detected with NGS (50) and FISH (5). Larotrectinib is an oral TKI that inhibits TRK across a diverse range of solid tumors in younger and older patients with NTRK gene–fusion positive disease. For the 2019 update (Version 3), the NCCN NSCLC Panel added a recommendation for NTRK gene fusion testing in patients with metastatic NSCLC based on recent data and the approval of larotrectinib for patients with NTRK gene fusion–positive disease.

**KRAS Mutations**

KRAS is a G-protein with GTPase activity that is part of the MAP/ERK pathway; point mutations in KRAS most commonly occur at codon 12. Data suggest that approximately 25% of patients with adenocarcinomas in a North American population have KRAS mutations; KRAS is the most common mutation in this population. KRAS mutation prevalence is associated with cigarette smoking. Patients with KRAS mutations appear to have a shorter survival than patients with wild-type KRAS; therefore, KRAS mutations are prognostic biomarkers. KRAS mutational status is also predictive of lack of therapeutic efficacy with EGFR TKIs; it does not appear to affect chemotherapeutic efficacy. KRAS mutations do not generally overlap with EGFR mutations, ALK rearrangements, or ROS1 rearrangements. Therefore, KRAS testing may identify patients who may not benefit from further molecular testing. Targeted therapy is not currently available for patients with KRAS mutations, although immune checkpoint inhibitors appear to be effective; MEK inhibitors are in clinical trials.

**PD-L1 Expression Levels**

Human immune-checkpoint–inhibitor antibodies inhibit the PD-1 receptor or PD-L1, which improves antitumor immunity; PD-1 receptors are expressed on activated cytotoxic T cells (see Immune Checkpoint Inhibitors in this Discussion). Nivolumab and pembrolizumab inhibit PD-1 receptors. Atezolizumab and durvalumab inhibit PD-L1. The NCCN NSCLC Panel recommends (category 1) IHC testing for PD-L1 expression ideally before first-line treatment in patients with metastatic NSCLC to assess whether PD-1 or PD-L1 inhibitors with or without chemotherapy are an option (see Pembrolizumab and Atezolizumab in this Discussion). The panel revised the recommendation for PD-L1 IHC testing to category 1 (from category 2A) for the 2019 update (Version 1) based on phase 3 randomized trial data.

For the 2019 update (Version 1), the NCCN NSCLC Panel added new first-line treatment regimens based on PD-L1 expression levels for patients with metastatic NSCLC, negative or unknown test results for EGFR mutations and ALK rearrangements, and no contraindications to immunotherapy (eg, no active or previously documented autoimmune disease and/or no current use of immunosuppressive agents, or no oncogene that would predict lack of benefit). Single-agent pembrolizumab is recommended as first-line therapy for patients with metastatic NSCLC regardless of histology, PD-L1 levels of 50% or more (category 1 preferred), and negative or unknown test results for EGFR mutations and ALK rearrangements. For the 2019 update (Version 4), the NCCN NSCLC Panel added another recommendation for single-agent pembrolizumab as first-line therapy in patients with metastatic NSCLC regardless of histology, PD-L1 levels of 1% to 49% (category 2B), and negative or unknown test results for EGFR mutations and ALK rearrangements (see Pembrolizumab in this Discussion).

The NCCN NSCLC Panel clarified the recommendations for pembrolizumab/chemotherapy in patients with metastatic nonsquamous NSCLC and PD-L1 expression levels of 1% to 49% for the 2019 update (Version 5); all of the regimens are preferred category 1 recommendations.
in this setting. Thus, the pembrolizumab/carboplatin (or cisplatin)/pemetrexed regimens are category 1 recommended options for patients with metastatic nonsquamous NSCLC regardless of PD-L1 expression levels; however, these regimens are preferred for those whose PD-L1 levels are less than 50% or unknown. First-line combination therapy with atezolizumab/bevacizumab/chemotherapy is category 1 recommended option for patients with nonsquamous NSCLC with negative or unknown test results for EGFR mutations and ALK rearrangements, regardless of PD-L1 expression levels.

The NCCN NSCLC Panel also clarified the recommendations for pembrolizumab/carboplatin/paclitaxel (or albumin-bound paclitaxel) in patients with metastatic squamous cell carcinoma NSCLC and PD-L1 expression levels of 1% to 49% for the 2019 update (Version 5); these regimens are a preferred category 1 recommendation in this setting. The pembrolizumab/carboplatin/paclitaxel (or albumin-bound paclitaxel) regimens are category 1 recommended options for patients with squamous cell carcinoma NSCLC regardless of PD-L1 expression levels; however, these regimens are preferred for those whose PD-L1 levels are less than 50% or unknown. Pembrolizumab/cisplatin/paclitaxel (or albumin-bound paclitaxel) is a category 2A recommended option for patients with squamous cell carcinoma NSCLC whose PD-L1 levels are less than 50%. For patients with medical contraindications to immunotherapy, the initial cytotoxic regimens are recommended depending on histology (eg, carboplatin/paclitaxel). Regardless of PD-L1 expression levels, subsequent therapy with a single-agent PD-1 or PD-L1 inhibitor appears to be less effective in tumors with EGFR mutations or ALK rearrangements based on data in the second-line setting.

A small study suggests that single-agent pembrolizumab is not effective as first-line therapy in patients with metastatic NSCLC and EGFR mutations, even those with PD-L1 levels more than 50%. Although it is not an optimal biomarker, PD-L1 expression is currently the best available biomarker to assess whether patients are candidates for PD-1 or PD-L1 inhibitors. Testing for PD-L1 is not required for prescribing single-agent nivolumab or atezolizumab for subsequent therapy. PD-L1 expression is continuously variable and dynamic; thus, a cutoff value for a positive result is artificial. Patients with PD-L1 expression levels just below and just above 50% will probably have similar responses. Unique anti-PD-L1 IHC assays have been developed for each of the different immune checkpoint inhibitors. The definition of a positive PD-L1 test result varies depending on which biomarker assay is used. Extensive effort has been undertaken to examine the cross-comparability of different clones with regard to each other to facilitate adoption of testing.

Treatment Approaches

Surgery, RT, and systemic therapy are the 3 modalities most commonly used to treat patients with NSCLC. They can be used either alone or in combination depending on the disease status. In the following sections, the clinical trials are described that have led to the recommended treatments. For tools to aid optimal assessment and management of older adults, see the NCCN Guidelines for Older Adult Oncology (available at www.NCCN.org). Older adults may be at risk for treatment-related adverse events.

Surgery

In general, for patients with stage I or II disease, surgery provides the best chance for cure. Thoracic surgical oncology consultation should be part of the evaluation of any patient being considered for curative local therapy. The overall plan of treatment and the necessary imaging studies should be determined before any nonemergency treatment is initiated. It is essential to determine whether patients can tolerate surgery or whether they are medically inoperable; some patients deemed inoperable may be able to...
tolerate minimally invasive surgery and/or sublobar resection.\textsuperscript{296-300}

Although frailty is an increasingly recognized predictor of surgical and other treatment morbidity, a preferred frailty assessment system has not been established.\textsuperscript{301-303}

The \textit{Principles of Surgical Therapy} are described in the NSCLC algorithm and are summarized here (see the NCCN Guidelines for NSCLC).

Determination of resectability, surgical staging, and pulmonary resection should be performed by board-certified thoracic surgeons who should participate in multidisciplinary clinics and/or tumor boards for patients with lung cancer. Surgery may be appropriate for select patients with uncommon types of lung cancer (eg, superior sulcus, chest wall involvement) (see the NCCN Guidelines for NSCLC).\textsuperscript{304} Patients with pathologic stage II or greater disease can be referred to a medical oncologist for evaluation. For resected stage IIIA, consider referral to a radiation oncologist. Treatment delays, because of poor coordination among specialists, should be avoided.

The surgical procedure used depends on the extent of disease and on the cardiopulmonary reserve of the patient. Lung-sparing anatomic resection (sleeve lobectomy) is preferred over pneumonectomy, if anatomically appropriate and if margin-negative resection can be achieved; lobectomy or pneumonectomy should be done if physiologically feasible.\textsuperscript{296,305,306}

Sublobular resection, either segmentectomy (preferred) or wedge resection, is appropriate in select patients; the parenchymal resection margins are defined in the NSCLC algorithm (see \textit{Principles of Surgical Therapy} in the NCCN Guidelines for NSCLC).\textsuperscript{307-311} Resection (including wedge resection) is preferred over ablation.\textsuperscript{296,306} Wide wedge resection may improve outcomes.\textsuperscript{312} Patients with medically inoperable disease may be candidates for SABR, also known as stereotactic body RT (SBRT).\textsuperscript{313,314} If SABR is considered for patients at high risk, a multidisciplinary evaluation is recommended (see \textit{Stereotactic Ablative Radiotherapy} in this Discussion).\textsuperscript{315-317}

**Lymph Node Dissection**

A randomized trial (ACOSOG Z0030) compared systematic mediastinal lymph node sampling versus complete lymphadenectomy during pulmonary resection in patients with either N0 (no demonstrable metastasis to regional lymph nodes) or N1 (metastasis to lymph nodes in the ipsilateral peribronchial and/or hilar region, including direct extension) NSCLC disease. In patients with early-stage disease who had negative nodes by systematic lymph node dissection, complete mediastinal lymph node dissection did not improve survival.\textsuperscript{318,319} Thus, systematic lymph node sampling is appropriate during pulmonary resection; one or more nodes should be sampled from all mediastinal stations. For right-sided cancers, an adequate mediastinal lymphadenectomy should include stations 2R, 4R, 7, 8, and 9. For left-sided cancers, stations 4L, 5, 6, 7, 8, and 9 should be sampled.\textsuperscript{318} Patients should have N1 and N2 node resection and mapping (American Thoracic Society map) with a minimum of 3 N2 stations sampled or a complete lymph node dissection.\textsuperscript{120} The lymph node map from the IASLC may be useful.\textsuperscript{320} Formal ipsilateral mediastinal lymph node dissection is indicated for patients undergoing resection for stage IIIA (N2) disease. For patients undergoing sublobular resection, the appropriate N1 and N2 lymph node stations should be sampled unless not technically feasible because sampling would substantially increase the surgical risk.

Sublobular resection, either segmentectomy (preferred) or wedge resection, is appropriate in select patients (see \textit{Principles of Surgical Therapy} in the NCCN Guidelines for NSCLC): 1) those who are not eligible for lobectomy; and 2) those with a peripheral nodule 2 cm or less with very low-risk features. Segmentectomy (preferred) or wedge resection
should achieve parenchymal resection margins that are: 1) 2 cm or more; or 2) the size of the nodule or larger.

**Stage IIIA N2 Disease**
The role of surgery in patients with pathologically documented stage IIIA (N2) disease is described in the NSCLC algorithm (see *Principles of Surgical Therapy* in the NCCN Guidelines for NSCLC) and summarized here. Before treatment, it is essential to carefully evaluate for N2 disease using radiologic and invasive staging (ie, EBUS-guided procedures, mediastinoscopy, thorascopic procedures) and to discuss whether surgery is appropriate in a multidisciplinary team, which should include a board-certified thoracic surgeon. Randomized controlled trials suggest that surgery does not increase survival in these patients;

However, one of these trials (EORTC) only enrolled patients with unresectable disease. Most clinicians agree that resection is appropriate for patients with negative preoperative mediastinal nodes and with a single positive node (<3 cm) found at thoracotomy. Neoadjuvant (preoperative) therapy is recommended for select patients. The optimal timing of RT in trimodality therapy (preoperative with chemotherapy or postoperative) is not established and controversial. In patients with N2 disease, 50% of the NCCN Member Institutions use preoperative chemoradiotherapy whereas 50% use preoperative chemotherapy. There is no evidence that adding RT to induction regimens improves outcomes for patients with stage IIIA (N2) disease when compared with using chemotherapy alone. Clinicians also agree that resection is not appropriate for patients with multiple pathologically proven malignant lymph nodes greater than 3 cm; definitive chemoradiotherapy is recommended for these patients.

The NCCN NSCLC Panel believes that surgery may be appropriate for select patients with N2 disease, especially those whose disease responds to induction chemotherapy (see *Principles of Surgical Therapy* in the NCCN Guidelines for NSCLC). It is controversial whether pneumonectomy after preoperative chemoradiotherapy is appropriate. Patients with resectable N2 disease should not be excluded from surgery, because some of them may have long-term survival or may be cured.

**Thorascopic Lobectomy**
Video-assisted thoracic surgery (VATS), which is also known as thorascopic lobectomy, is a minimally invasive surgical treatment that is currently being investigated in all aspects of lung cancer (see *Principles of Surgical Therapy* in the NCCN Guidelines for NSCLC). Published studies suggest that thorascopic lobectomy has several advantages over thoracotomy. Acute and chronic pain associated with thorascopic lobectomy is minimal; thus, this procedure requires a shorter length of hospitalization. Thorascopic lobectomy is also associated with low postoperative morbidity and mortality, minimal risk of intraoperative bleeding, or minimal locoregional recurrence. Thorascopic lobectomy is associated with less morbidity, fewer complications, and more rapid return to function than lobectomy by thoracotomy.

In patients with stage I NSCLC who had thorascopic lobectomy with lymph node dissection, the 5-year survival rate, long-term survival, and local recurrence were comparable to those achieved by routine open lung resection. Thorascopic lobectomy has also been shown to improve discharge independence in older populations and patients at high risk. Data show that thorascopic lobectomy improves the ability of patients to complete postoperative chemotherapy regimens. Based on its favorable effects on postoperative recovery and morbidity, thorascopic lobectomy (including robotic-assisted approaches) is recommended in the NSCLC algorithm as an acceptable approach for patients who are surgically resectable (and have no anatomic or surgical contraindications) as long as principles of thoracic surgery are not compromised.
for NSCLC).\textsuperscript{365-368} Robotic VATS seems to be more expensive with longer operating times than conventional VATS.\textsuperscript{369,370}

**Radiation Therapy**

The *Principles of Radiation Therapy* in the NSCLC algorithm include the following: 1) general principles for early-stage, locally advanced, and advanced/metastatic NSCLC; 2) target volumes, prescription doses, and normal tissue dose constraints for early-stage, locally advanced, and advanced/metastatic NSCLC; and 3) RT simulation, planning, and delivery.\textsuperscript{371-376} These RT principles are summarized in this section. Whole brain RT and SRS for brain metastases are also discussed in this section. The abbreviations for RT are defined in the NSCLC algorithm (see Table 1 in *Principles of Radiation Therapy* in the NCCN Guidelines for NSCLC). For the 2019 update (Version 1), the NCCN NSCLC Panel extensively revised the RT recommendations in the algorithm (see *Principles of Radiation Therapy* in the NCCN Guidelines for NSCLC). For example, some of the normal tissue dose constraints for conventionally fractionated RT were revised (see Table 5).

**General Principles**

Treatment recommendations should be made by a multidisciplinary team. Because RT has a potential role in all stages of NSCLC, as either definitive or palliative therapy, input from board-certified radiation oncologists who perform lung cancer RT as a prominent part of their practice should be part of the multidisciplinary evaluation or discussion for all patients with NSCLC. Uses of RT for NSCLC include: 1) definitive therapy for locally advanced NSCLC, generally combined with chemotherapy; 2) definitive therapy for early-stage NSCLC in patients with contraindications for surgery; 3) preoperative or postoperative therapy for selected patients treated with surgery; 4) therapy for limited recurrences and metastases; and/or 5) palliative therapy for patients with incurable NSCLC.\textsuperscript{317,377-384} The goals of RT are to maximize tumor control and to minimize treatment toxicity. Advanced technologies such as 4D-conformal RT simulation, intensity-modulated RT/volumetric modulated arc therapy (IMRT/VMAT), image-guided RT, motion management strategies, and proton therapy have been shown to reduce toxicity and increase survival in nonrandomized trials.\textsuperscript{385-391} A secondary analysis of a randomized trial (RTOG 0617) reported that 2-year overall survival, PFS, local failure, and distant metastasis-free survival were not significantly different for IMRT when compared with 3D-conformal RT. IMRT yielded lower rates of severe pneumonitis when compared with 3D-conformal RT (3.5% vs. 7.9%; \( P = .039 \)).\textsuperscript{392} CT-planned 3D-conformal RT is now considered to be the minimum level.

**Radiation Simulation, Planning, and Delivery**

Simulation should be performed using CT scans obtained in the RT treatment position. Intravenous contrast CT scans, with or without oral contrast, are recommended for better target delineation whenever possible, especially in patients with central tumors or nodal involvement. FDG PET/CT can significantly improve target delineation accuracy, especially when there is atelectasis or contraindications to intravenous CT contrast.\textsuperscript{393,394} Ideally, PET/CT should be obtained 4 weeks before treatment because of the potential for rapid progression of NSCLC.\textsuperscript{395,396} In the NSCLC algorithm, recommendations are provided for patients receiving chemoradiation (including those with compromised lung or cardiac function), photon beams, or IMRT (see *Radiation Therapy Simulation, Planning, and Delivery* in the *Principles of Radiation Therapy* in the NCCN Guidelines for NSCLC).\textsuperscript{390,397-400} Respiratory motion should be managed. The report from the AAPM Task Group 76 is a useful reference for implementing a broad range of motion management strategies as described in the NSCLC algorithm (see *Radiation Therapy Simulation, Planning, and Delivery* in the NCCN Guidelines for NSCLC).\textsuperscript{401}
Target Volumes, Prescription Doses, and Normal Tissue Dose Constraints

Commonly used prescription RT (or SABR) doses and normal tissue dose constraints are summarized in the Principles of Radiation Therapy in the NSCLC algorithm (see Tables 2–5 in the NCCN Guidelines for NSCLC). Reports 50, 62, and 83 from the International Commission on Radiation Units and Measurements provide a formalism for defining RT target volumes based on grossly visible disease, potential microscopic extension, and margins for target motion and daily positioning uncertainty. The ACR Practice Parameters and Technical Standards are also a helpful reference. It is essential to evaluate the dose-volume histogram (DVH) of critical structures and to limit the doses to the organs at risk (such as spinal cord, lungs, heart, esophagus, and brachial plexus) to minimize normal tissue toxicity (see Table 5 in Principles of Radiation Therapy). For patients receiving postoperative RT (also known as PORT), stricter DVH parameters should be considered for the lungs. The QUANTEC review provides the most comprehensive estimates from clinical data of dose-response relationships for normal tissue complications.

For the 2019 update (Version 1), some of the normal tissue dose constraints for conventionally fractionated RT were revised based on a survey of radiation oncologists at NCCN Member Institutions (see Table 5 in Principles of Radiation Therapy in the NCCN Guidelines for NSCLC). These constraints are mainly empirical and have not, for the most part, been validated rigorously. Therefore, the doses and constraints provided in the tables are not specific prescriptive recommendations; they are useful reference doses that have been commonly used or are from previous clinical trials. A caveat was added for the 2019 update (Version 1) that these constraints represent doses that generally should not be exceeded. Because the risk of toxicity increases progressively with dose to normal tissues, a key principle of radiation treatment planning is to keep normal tissue doses "as low as reasonably achievable" while adequately covering the target. The doses to any given organ at risk should typically be lower than these constraints, approaching them only when there is close proximity to the target volume. After surgery, lung tolerance to RT is much less than for patients with intact lungs; therefore, more conservative constraints should be used for postoperative RT.

For definitive RT, the commonly prescribed dose is 60 to 70 Gy in 2 Gy fractions over 6 to 7 weeks. The use of higher RT doses is discussed in the NSCLC algorithm (see Principles of Radiation Therapy in the NCCN Guidelines for NSCLC). Doses more than 74 Gy are not currently recommended for routine use. Results from a phase 3 randomized trial (RTOG 0617) suggest that high-dose radiation using 74 Gy with concurrent chemotherapy does not improve survival, and might be harmful, when compared with a dose of 60 Gy. Although optimal RT dose intensification remains a valid question, at higher RT doses, normal tissue constraints become even more important. Although the RT dose to the heart was decreased in the RTOG 0617 trial, survival was decreased; thus, more stringent constraints may be appropriate.

General Treatment Information

The RT recommendations for patients with stages I to IV are described in the NSCLC algorithm (see Principles of Radiation Therapy in the NCCN Guidelines for NSCLC).

Definitive RT, particularly SABR, is recommended for patients with early-stage NSCLC (ie, stage I-II, N0) who are medically inoperable or those who refuse surgery (see Stereotactic Ablative Radiotherapy in this Discussion). Interventional radiology ablation is an option for selected patients who are medically inoperable. By extrapolation from surgical data, chemotherapy (category 2B) may be considered after definitive RT/SABR in patients with high-risk factors for recurrence (eg, large tumors >4 cm in size). SABR is also an option...
for patients at high surgical risk who cannot tolerate a lobectomy (eg, major medical comorbidity or severely limited lung function). Resection is recommended for patients with early-stage NSCLC who are medically fit (see Principles of Surgical Therapy in the NCCN Guidelines for NSCLC). The indications for using preoperative or postoperative chemoradiation or RT alone are described in the NSCLC algorithm (see Principles of Radiation Therapy in the NCCN Guidelines for NSCLC). In patients with clinical stage I or II NSCLC who are upstaged to N2+ after surgery, postoperative chemotherapy can be administered followed by postoperative RT depending on the margin status (see the NCCN Guidelines for NSCLC). Postoperative RT has been associated with increased mortality in patients with pathologic stage N0 to 1 disease, although the study used older RT techniques.

Definitive chemoradiation is recommended for patients with stage II to III disease who are not appropriate surgical candidates. For patients with locally advanced NSCLC (stage III), the most commonly prescribed conventionally fractionated doses for definitive RT are 60 to 70 Gy in 2 Gy fractions. Doses of at least 60 Gy should be given. Dose escalation is associated with better survival in non-randomized comparisons in RT alone, sequential chemo/RT, or concurrent chemo/RT. A meta-analysis demonstrated improved survival with accelerated fractionation RT regimens. Involved-field RT (also known as involved-field irradiation or IFI) is an option for treating nodal disease in patients with locally advanced NSCLC; IFI may offer advantages over elective nodal irradiation (ENI).

The optimal management of patients with potentially operable stage IIIA NSCLC is controversial and is discussed in detail in the algorithm (see Principles of Surgical Therapy in the NCCN Guidelines for NSCLC). For patients undergoing preoperative therapy before surgical resection of stage IIIA NSCLC, some oncologists prefer chemotherapy alone rather than chemoradiotherapy for the preoperative treatment; RT should generally be given postoperatively if not given preoperatively. The NCCN NSCLC Panel recommends a preoperative RT dose of 45 to 54 Gy in 1.8 to 2 Gy fractions. Definitive RT doses delivered as preoperative chemo/RT can safely be administered and achieve promising nodal clearance and survival rates; the risk of surgical complications after high-dose RT can be minimized with expert thoracic surgical techniques. NCCN Member Institutions are evenly split in their use of preoperative chemotherapy versus preoperative chemoradiation in patients with stage IIIA N2 NSCLC. Similarly, some consider the need for pneumonectomy to be a contraindication to a combined modality surgical approach given the excess mortality observed in clinical trials, but NCCN Member Institutions are split on this practice as well.

In postoperative RT, the clinical target volume (CTV) includes the bronchial stump and high-risk draining lymph node stations. Standard doses after complete resection are 50 to 54 Gy in 1.8 to 2 Gy fractions, but a boost may be administered to high-risk regions including areas of nodal extracapsular extension or microscopic positive margins. Lung dose constraints should be more conservative, because tolerance appears to be reduced after surgery. The ongoing European LungART trial provides useful guidelines for postoperative RT technique. Surgery is associated with potentially greater risk of complications, particularly stump breakdown and bronchopleural fistula, in a field that has had high-dose RT (eg, 60 Gy). Thus, surgeons are often wary of resection in areas that have previously received RT doses of more than 45 to 50 Gy, especially in patients who have received definitive doses of concurrent chemoradiation (ie, ≥60 Gy) preoperatively. Soft tissue flap coverage and reduced intraoperative fluid administration and ventilator pressures can reduce the risk of these complications. When giving preoperative RT to less than definitive doses (eg, 45 Gy), one should be prepared up...
front to continue to a full definitive dose of RT without interruption if the patient does not proceed to surgery for some reason. For these reasons, when considering trimodality therapy, the treatment plan—including assessment for resectability and the type of resection—should be decided before initiation of any therapy.

For patients with advanced lung cancer (ie, stage IV) with extensive metastases, systemic therapy is recommended; palliative RT can be used for symptom relief and potentially for prophylaxis at primary or distant sites (such as pain, bleeding, or obstruction). Shorter courses of palliative RT are preferred for patients with symptomatic chest disease who have poor PS and/or shorter life expectancy (eg, 17 Gy in 8.5 Gy fractions), because they provide similar pain relief as longer courses, although there is a higher potential need for retreatment (see Table 4 in the Principles of Radiation Therapy in the NCCN Guidelines for NSCLC). Higher dose and longer course thoracic RT (eg, ≥30 Gy in 10 fractions) are associated with modestly improved survival and symptoms, especially in patients with good PS. When higher doses (>30 Gy) are warranted, technologies to reduce normal tissue irradiation may be used (at least 3D-CRT and including IMRT or proton therapy as appropriate).

Local therapy (RT, SABR, or surgery) to primary and oligometastatic lesions should be considered for patients without progression on systemic therapy. Definitive local therapy to isolated or limited metastatic sites (oligometastases) (including but limited to brain, lung, and adrenal gland) achieves prolonged survival in a small proportion of well-selected patients with good PS who have also received radical therapy to the intrathoracic disease. Definitive RT to oligometastases, particularly SABR, is an appropriate option in such cases if it can be delivered safely to the involved sites. In 2 randomized phase II trials, significantly improved PFS was found for local consolidative therapy (RT or surgery) to primary and oligometastatic lesions versus maintenance systemic therapy or observation for patients not progressing on systemic therapy.

### Stereotactic Ablative Radiotherapy

SABR (also known as SBRT) uses short courses of very high (ablative), highly conformal, and dose-intensive RT precisely delivered to limited-size targets. Studies, including prospective multi-institutional trials, have demonstrated the efficacy of SABR for patients with inoperable stage I NSCLC or for those who refuse surgery. With conventionally fractionated RT, 3-year survival is only about 20% to 35% in these patients, with local failure rates of about 40% to 60%. In prospective clinical trials, local control and overall survival appear to be considerably increased with SABR, generally more than 85%, and about 60% at 3 years (median survival, 4 years), respectively, in patients who are medically inoperable. A 7-year follow-up of 65 patients with medically inoperable stage I NSCLC reported that overall survival rates were 55.7% at 5 years and 47.5% at 7 years. In 12 patients (18.5%), a second primary lung carcinoma developed after SABR at a median of 35 months (range, 5–67 months); 27% (18/65) had disease recurrence a median of 14.5 months (range, 4.3–71.5 months) after SABR.

Substantially higher survival has been observed in patients with potentially operable disease who are treated with SABR; survival is comparable in population-based comparisons to surgical outcomes, but locoregional recurrences are more frequent. It has not been shown that use of SABR for medically operable patients provides long-term outcomes equivalent to surgery. Late recurrences have been reported more than 5 years after SABR, highlighting the need for careful surveillance. If possible, biopsy should confirm NSCLC before use of SABR. SABR is recommended in the NSCLC algorithm for patients with stage I and II (T1–3,N0,M0) NSCLC who are medically inoperable; SABR is a reasonable alternative to surgery for patients with potentially operable
SABR fractionation regimens and a limited subset of historically used maximum dose constraints are provided in the NSCLC algorithm; 1 to 5 fractions are generally used (see Tables 2 and 3 in the Principles of Radiation Therapy in the NCCN Guidelines for NSCLC). In the United States, only regimens of 5 fractions or less meet the arbitrary billing code definition for SABR; however, slightly more protracted regimens are also appropriate. Prescription doses do not completely describe the actual delivered doses. These dose constraints are point-of-reference doses and are not intended to be prescriptive; they are used commonly or have been used in clinical trials. Although none of these dose constraints has been validated as a maximally tolerated dose, outcomes of clinical trials to date suggest that they are safe constraints.

SRS or SABR for limited oligometastases to the brain or other body sites, respectively, is recommended for patients with good PS if their thoracic disease can be treated with definitive therapy (see Stage IV, M1b in the NCCN Guidelines for NSCLC). SRS or SABR can be considered for select patients with stage M1c disease who have a limited number and volume of metastatic lesions that are amenable to treatment with definitive local therapy; limited number is not defined but clinical trials have included up to 3 to 5 small metastases. Targeted therapy and consideration of local therapy (eg, surgery or SABR [or SRS] for isolated lesions) is recommended for patients with ALK rearrangements or sensitizing EGFR mutations who have progressed on targeted therapy, depending on the type of progression.

Decisions about whether to recommend SABR should be based on multidisciplinary discussion. Hypofractionated or dose-intensified conventional 3D-conformal RT is an option if an established SABR program is not available. Nonrandomized clinical data indicate that local tumor control with SABR is higher than with interventional radiology ablation techniques. Interventional radiology ablation may be appropriate for selected patients for whom local control is not necessarily the highest priority.

Whole Brain RT and Stereotactic Radiosurgery

Many patients with NSCLC have brain metastases (30%–50%), which substantially affect their quality of life. Options for treatment of limited brain metastases include: 1) SRS alone; and 2) surgical resection for selected patients followed by SRS or whole brain RT. Selected patients...
include those with symptomatic metastases or whose tumor tissue is needed for diagnosis (see the NCCN Guidelines for NSCLC). Treatment of limited brain metastases in patients with NSCLC differs from that recommended in the NCCN Guidelines for Central Nervous System Cancers, because patients with NSCLC and brain metastases often have long-term survival; therefore, the potential neurocognitive issues that may occur with whole brain RT are a concern. Clinicians are not using whole brain RT as often in patients with limited brain metastases.

A randomized trial assessed cognitive function in 213 patients with 1 to 3 brain metastases who received SRS alone versus SRS with whole brain RT; most patients had lung cancer. At 3 months after SRS alone, patients had less cognitive deterioration (40/63 patients [63.5%]) than those receiving SRS plus whole brain RT (44/48 patients [91.7%]; difference, -28.2%; 90% CI, -41.9% to -14.4%; P < .001). Decisions about whether to recommend SRS alone or brain surgery followed by whole brain RT or SRS for limited brain metastases should be based on multidisciplinary discussion, weighing the potential benefit over the risk for each individual patient. Treatment should be individualized for patients with recurrent or progressive brain lesions.

For multiple metastases (eg, >3), whole brain RT is recommended; SRS may be preferred for patients who have good PS and low systemic tumor burden (see the NCCN Guidelines for Central Nervous System Cancers, available at www.NCCN.org). Whole brain RT is associated with measurable declines in neurocognitive function in clinical trials, particularly with increasing dose and advanced age of the patient. However, control of brain metastases confers improved neurocognitive function. For limited metastases, randomized trials have found that the addition of whole brain RT to SRS decreases intracranial recurrence but does not improve survival and may increase the risk of cognitive decline. Thus, SRS or whole brain RT alone is recommended for patients with limited volume metastases. Some have suggested that resection followed by SRS to the cavity (instead of resection followed by whole brain RT) will decrease the risk of neurocognitive problems. A study suggests that using IMRT to avoid the hippocampus may help decrease memory impairment after whole brain RT. A phase 3 randomized trial assessed optimal supportive care (including dexamethasone) with whole brain RT versus optimal supportive care alone in patients with NSCLC and brain metastases who were not eligible for brain surgery or SRS. Overall survival was similar between the groups (HR, 1.06; 95% CI, 0.90–1.26). Overall quality of life, use of dexamethasone, and reported adverse events were also similar between the arms.

Combined Modality Therapy

As previously mentioned, surgery provides the best chance for cure for patients with stage I or II disease who are medically fit and can tolerate surgery. SABR can be considered for patients with unresectable stage I or II (T1–3, N0) disease or those who refuse surgery if their disease is node negative (see Stereotactic Ablative Radiotherapy in this Discussion and see the NCCN Guidelines for NSCLC). In patients with completely resected NSCLC, adjuvant (postoperative) chemotherapy has been shown to improve survival in patients with early-stage disease. Some studies suggest that preoperative chemotherapy (also referred to as neoadjuvant chemotherapy or induction chemotherapy) is as effective as and better tolerated than postoperative chemotherapy (see Preoperative Chemotherapy Followed by Surgery: Trial Data in this Discussion). A randomized trial found no difference in survival with preoperative versus postoperative chemotherapy. The NCCN Guidelines state that patients with stage II or IIIA (T3, N1) disease may be treated with induction chemotherapy before surgery if they are candidates for therapy after surgery. Concurrent chemoradiation is more efficacious than
sequential chemoradiation for patients with unresectable stage III disease.590-593

For patients with stage IV disease who have a good PS, platinum-based chemotherapy is beneficial.594-599 Data show that early palliative care combined with systemic therapy improved quality of life, mood, and survival in patients with metastatic NSCLC, even if these patients had less aggressive end-of-life care, when compared with those not receiving palliative care alone.600,601 Patients should receive treatment for debilitating symptoms.12,602,603 A study also suggests that social support, such as being married, is as effective as systemic therapy.604 Preliminary results from a recent study indicate that systematic symptom monitoring during outpatient chemotherapy treatment increases overall survival when compared with usual care.605 Surgery is rarely recommended for patients with stage IV disease. However, surgical resection of limited brain metastases may improve survival in selected patients with stage IV disease and is recommended for selected patients in the NCCN Guidelines (see the NCCN Guidelines for NSCLC, available at www.NCCN.org).606 Definitive local therapy with surgical resection or RT is recommended for limited single-organ metastases located in sites other than the brain if definitive thoracic therapy is feasible (see Stage IVA, M1b in the NCCN Guidelines for NSCLC).304,476,478,489,538,539 The trials supporting the recommendations for combined modality therapy are discussed in the following sections.

Surgery Followed by Chemotherapy: Trial Data

In the NSCLC algorithm for resected stage IA disease, postoperative chemotherapy is not recommended based on the trials described in the following paragraphs.607 Postoperative chemotherapy may be considered for high-risk, margin-negative, stage IB disease (see the NCCN Guidelines for NSCLC). Recommended chemotherapy regimens for preoperative and postoperative therapy are provided in the NCCN Guidelines.577,607 The NCCN NSCLC Panel recently added 2 preoperative and postoperative therapy regimens for patients with comorbidities or those not able to tolerate cisplatin, including 1) carboplatin/gemcitabine; and 2) carboplatin/pemetrexed (nonsquamous only).608-611

The International Adjuvant Lung Cancer Trial (IALT) reported a statistically significant survival benefit with cisplatin-based postoperative therapy in patients with completely resected stage I, II, or III NSCLC.578 The study included 1867 patients with surgically resected lung cancer who were randomly assigned either to cisplatin-based postoperative chemotherapy or to observation, with a median follow-up duration of 56 months. A higher survival rate (45% vs. 40% at 5 years; HR for death, 0.86; 95% CI, 0.76–0.98; P < .03) and disease-free survival rate (39% vs. 34% at 5 years; HR, 0.83; 95% CI, 0.74–0.94; P < .003) were reported for patients assigned to chemotherapy when compared with observation. IALT data suggest that cisplatin-based postoperative chemotherapy improves survival 5 years after treatment in patients with completely resected NSCLC. However, after 7.5 years of follow-up, there were more deaths in the chemotherapy group and the benefit of chemotherapy decreased over time.612 Data show that postoperative chemotherapy prevents recurrences.

The NCIC CTG JBR.10 trial and the ANITA trial compared the effectiveness of postoperative vinorelbine/cisplatin versus observation in early-stage NSCLC. In the JBR.10 trial, 482 patients (ECOG PS of 0–1) with completely resected stage IB (T2a,N0) or stage II (T1,N1, or T2,N1) NSCLC were randomly assigned either to vinorelbine/cisplatin or to observation.579 Postoperative chemotherapy significantly prolonged overall survival (94 vs. 73 months; HR for death, 0.69; P = .04) and relapse-free survival (not reached vs. 47 months, HR for recurrence, 0.60; P < .001) when compared with observation alone. The 5-year survival rates were 69% and 54%, respectively (P = .03). When compared with observation alone, postoperative chemotherapy is beneficial for patients with stage II
disease but not for stage IB disease as shown by updated data from JBR.10 after 9 years of follow-up. In patients with stage II disease receiving postoperative chemotherapy, median survival is 6.8 versus 3.6 years in those who were only observed. Of note, patients receiving chemotherapy did not have an increased death rate.

In the ANITA trial, 840 patients with stage IB (T2aN0), II, or IIIA NSCLC were randomly assigned either to postoperative vinorelbine/cisplatin or to observation. Grade 3/4 toxicities were manageable in the chemotherapy group; 7 toxic deaths were reported. After a median follow-up of 76 months, median survival was 66 months in the chemotherapy group and 44 months in the observation group. Postoperative chemotherapy significantly improved (8.6%) the 5-year overall survival in patients with completely resected stage II and IIIA disease, although no benefit was observed in stage I. Some clinicians consider vinorelbine/cisplatin to be the preferred regimen for completely resected early-stage NSCLC based on the number of trials and the amount of use; however, most clinicians in the United States prefer to use regimens with less toxicity.

A meta-analysis of 4,584 patients (LACE) found that postoperative cisplatin-based chemotherapy increased survival over 5 years (absolute benefit of 5.4%); there was no difference among the chemotherapy regimens (vinorelbine, etoposide, and others). A subgroup analysis found that cisplatin/vinorelbine also increased survival. The benefit was greater in patients with stage II and III disease and with good PS. Postoperative chemotherapy benefited elderly patients up to 80 years of age.

The CALGB 9633 trial assessed paclitaxel/carboplatin in patients with stage IB (T2aN0M0) lung cancer. In this trial, 344 patients were randomly assigned either to paclitaxel/carboplatin or to observation (within 4–8 weeks of resection) with a median follow-up duration of 74 months. Postoperative chemotherapy was well tolerated with no chemotherapy-related toxic deaths. Overall survival at 6 years was not significantly different (although a subset analysis showed a benefit for tumors 4 cm or more), although 3-year survival was significant (80% vs. 73%, P = .02). Thus, the carboplatin/paclitaxel regimen is only recommended for early-stage disease if patients cannot tolerate cisplatin (see Chemotherapy Regimens for Neoadjuvant and Adjuvant Therapy in the NCCN Guidelines for NSCLC). It is important to note that the CALGB trial was underpowered for patients with stage 1B disease.

Preoperative Chemotherapy Followed by Surgery: Trial Data

Data from clinical trials in patients with resected NSCLCs indicate that delivery of chemotherapy is an important problem. In the postoperative setting, significant comorbidities and incomplete recovery after surgery often make it difficult for patients to tolerate systemic therapy. This problem was demonstrated in the NATCH phase 3 trial (which compared surgery alone to preoperative or postoperative chemotherapy with paclitaxel/carboplatin), because 90% of the preoperative cohort completed 3 cycles of chemotherapy but only 61% of the postoperative cohort completed chemotherapy; however, survival was equivalent among all 3 arms. A randomized trial found no difference in 3-year overall survival (67.4% vs. 67.7%) with preoperative versus postoperative chemotherapy in patients with early-stage NSCLC; response rate and quality of life were similar in both arms. Postoperative chemotherapy (with or without RT or resection) is recommended and typically used for early-stage disease in the NCCN Guidelines.

Several trials suggest that preoperative therapy is beneficial in patients with N2 disease. Other trials suggest that preoperative therapy is beneficial in patients with earlier stage disease. A follow-up, randomized intergroup trial (SWOG 9900) evaluated preoperative paclitaxel/carboplatin in 354 patients with stage IB to IIIA (but not N2) disease versus surgery alone. The trial closed prematurely because of
practice changes and was therefore not appropriately powered. This SWOG trial did show a trend toward improved PFS (33 vs. 20 months) and overall survival (62 vs. 41 months) with preoperative chemotherapy, and no difference in resection rates between the 2 arms.587

Scagliotti et al published a phase 3 trial of preoperative cisplatin/gemcitabine versus surgery alone in 270 patients with stage IB to IIIA disease. Although the trial closed early, a significant survival benefit was seen in patients with stages IIB and IIIA disease who received chemotherapy (HR, 0.63).582 Song et al published a meta-analysis of all available randomized clinical trials evaluating preoperative chemotherapy in resectable NSCLCs. This meta-analysis evaluated 13 randomized trials; the HR suggests that overall survival in the preoperative chemotherapy arm is similar to the surgery alone arm (HR, 0.84; 95% CI, 0.77–0.92; P = .0001).581 These results are similar to those reported in another meta-analysis (HR, 0.89; 95% CI, 0.81–0.98; P = .02).582 The benefit from preoperative chemotherapy is similar to that attained with postoperative chemotherapy.582,588,617

Chemoradiation: Trial Data
The major controversies in NSCLC relate to the management of patients with stage IIIA disease (see the Role of Surgery in Patients with Stage IIIA (N2) NSCLC in Principles of Surgical Therapy in the NCCN Guidelines for NSCLC). All 3 treatment modalities—surgical resection, chemotherapy, and radiation—may be used when treating stage III disease. The ongoing debate centers on which modalities to use and in what sequence.524-628 For patients with unresectable stage IIIA or stage IIIB disease, combined modality therapy (chemoradiation) is more efficacious than radiation alone.624,625,627-629 Concurrent chemoradiation is more efficacious than sequential chemoradiation.590-593,630 However, concurrent chemoradiation has a higher rate of grade 3 or 4 esophagitis than sequential chemoradiation. Selection of patients should be based not only on the anticipated response to therapy but also on how well the patient is anticipated to tolerate therapy. Accelerated RT regimens may be useful if concurrent chemoradiation would not be tolerated.451,631 Sequential chemoradiation or RT alone is recommended for frail patients who cannot tolerate concurrent chemoradiation.297,632

A recent study reported that patients with N2 disease and an R0 resection had improved survival with postoperative chemotherapy followed by postoperative RT (ie, sequential chemoradiation) compared with postoperative concurrent chemoradiation (median overall survival, 58.8 vs. 40.4 months, respectively; P < .001).461 However, there was no difference in overall survival when patients with N2 disease and positive margins had postoperative sequential chemoradiation compared with postoperative concurrent chemoradiation (median overall survival, 42.6 vs. 38.5 months, respectively; P = .42). Although the optimal sequence is not established, postoperative RT is generally administered after adjuvant chemotherapy or concurrently for positive resection margins.372,374,375,633

Concurrent chemoradiation regimens that may be used for all histologies for initial treatment include cisplatin/etoposide, cisplatin/vinblastine, and carboplatin/paclitaxel (see Chemotherapy Regimens Used with Radiation Therapy in the NCCN Guidelines for NSCLC).434,590,592,634-638 For nonsquamous NSCLC, additional concurrent chemoradiation regimens may be used including carboplatin/pemetrexed and cisplatin/pemetrexed.639-641 A weekly paclitaxel/carboplatin regimen is another chemoradiation option.434 The different options for preoperative, definitive, and postoperative chemotherapy/RT are described in detail in the algorithm. Recently, the NCCN NSCLC Panel removed the preferred designation for the cisplatin/etoposide and cisplatin/vinblastine concurrent regimens based on data from a phase 3 randomized trial and a retrospective assessment of the Veterans Administration data.634,638,642 Recently, the NCCN NSCLC Panel expanded the list of regimens for
sequential chemoradiation to include regimens that are also used for preoperative and postoperative chemotherapy (ie, cisplatin combined with pemetrexed [nonsquamous only], docetaxel, etoposide, gemcitabine, or vinorelbine; carboplatin combined with paclitaxel) and also added 2 new carboplatin regimens for patients with comorbidities or those not able to tolerate cisplatin, including 1) carboplatin/gemcitabine; and 2) carboplatin/pemetrexed (nonsquamous only).

**Durvalumab**

Durvalumab is a human immune checkpoint inhibitor antibody that inhibits PD-L1 (see *PD-L1 Expression Levels* and *Immunotherapies* in this Discussion). A recent phase 3 randomized trial (PACIFIC) compared consolidation therapy (ie, after chemoradiation) with durvalumab versus placebo in patients with unresectable stage III NSCLC (PS 0–1) who had not progressed after 2 or more cycles of definitive concurrent platinum-based chemoradiation. Patients received durvalumab after receiving concurrent chemoradiation (1–42 days). Most patients were current or former smokers and did not have EGFR mutations; their PD-L1 status was typically less than 25% or unknown. An updated analysis of this trial reported that overall survival was increased after durvalumab consolidation when compared with placebo. The overall survival rate at 24 months was 66.3% for durvalumab (95% CI, 61.7%–70.4%) versus 55.6% for placebo (95% CI, 48.9%–61.8%). The PFS was 17.2 months for durvalumab (95% CI, 13.1–23.9) versus 5.6 months for placebo (95% CI, 4.6–7.7) (stratified HR for disease progression or death, 0.51; 95% CI, 0.41–0.63; *P* < .001). The median time to death or distant metastasis was significantly longer with durvalumab when compared with placebo (28.3 months vs. 16.2 months; *P* < .001). Patients receiving durvalumab had a higher ongoing response at 18 months when compared with placebo (73.5% vs. 52.2%). Durvalumab was effective in patients with both squamous and nonsquamous NSCLC. Grade 3 or 4 adverse events occurred at a similar rate in both groups of patients (durvalumab, 30.5% vs. placebo, 26.1%). Pneumonia was the most common grade 3 or 4 adverse event (durvalumab, 4.4% vs. placebo, 3.8%).

The NCCN NSCLC Panel recommends durvalumab (category 1) as consolidation immunotherapy (regardless of PD-L1 status) for patients (PS 0–1) with unresectable stage III NSCLC who have not progressed after 2 or more cycles of definitive concurrent platinum-based chemoradiation based on this trial. Durvalumab may be used as consolidation immunotherapy after any of the concurrent chemoradiation regimens described in the algorithm (eg, cisplatin/etoposide, carboplatin/paclitaxel) (see *Chemotherapy Regimens Used With Radiation Therapy* in the NCCN Guidelines for NSCLC). The panel noted that a few patients with stage II NSCLC were included in the PACIFIC trial, which used the older AJCC staging (7th edition). For the 2019 update (Version 1), the NCCN NSCLC Panel revised the durvalumab consolidation immunotherapy recommendation to category 1 (from category 2A) based on updated data from the PACIFIC trial. In addition, the panel deleted the recommendation to add an additional 2 cycles of full-dose chemotherapy if patients have not received full-dose chemotherapy concurrently with RT based on concerns that consolidation chemotherapy will increase the risk of pneumonitis if patients are also receiving durvalumab. Durvalumab should be discontinued for patients with severe or life-threatening pneumonitis and should be withheld or discontinued for other severe or life-threatening immune-mediated adverse events when indicated (see prescribing information). Consolidation chemotherapy is an option after concurrent chemoradiation for patients who are not receiving durvalumab because of medical contraindications or other reasons.

**Chemotherapy: Trial Data**

Patients with stage IV disease who have a good PS benefit from chemotherapy, usually with a platinum-based regimen.
Chemotherapy is recommended for patients with stage IV NSCLC and negative or unknown test results for ALK rearrangements or sensitizing EGFR mutations, PD-L1 expression less than 1% or unknown, and contraindications to immunotherapy. Recommended chemotherapy regimens are based on PS and include platinum agents (eg, cisplatin, carboplatin), taxanes (eg, paclitaxel, albumin-bound paclitaxel [also known as nab-paclitaxel], docetaxel), vinorelbine, etoposide, pemetrexed, and gemcitabine (see Systemic Therapy for Advanced or Metastatic Disease in the NCCN Guidelines for NSCLC). To clarify use of systemic therapy, the NCCN Guidelines list all of the combination systemic therapy regimens and single agents that are recommended for patients with metastatic NSCLC depending on histology and PS (see Systemic Therapy for Advanced or Metastatic Disease in the NCCN Guidelines for NSCLC). Combinations using many of these drugs produce 1-year survival rates of 30% to 40% and are more efficacious than single agents.252,622,644-646 In the United States, frequently used initial cytotoxic regimens for nonsquamous NSCLC include: 1) cisplatin (or carboplatin)/pemetrexed; or 2) carboplatin/paclitaxel with (or without) bevacizumab.647,648 Gemcitabine/cisplatin is recommended for patients with either squamous cell carcinoma or nonsquamous NSCLC.252,647-649 These regimens are recommended based on phase 3 randomized trials (eg, cisplatin/pemetrexed, carboplatin/paclitaxel [with or without bevacizumab], gemcitabine/cisplatin).251,252

The initial cytotoxic systemic therapy regimens were recently revised by deleting options that are less effective, more toxic, and/or infrequently used in the United States based on each panel member’s experience and data generated by surveying the NCCN NSCLC Panel (see the NCCN Guidelines With Evidence Blocks™ for NSCLC, available at www.NCCN.org). For patients with nonsquamous NSCLC, panel members deleted carboplatin/etoposide, carboplatin/vinorelbine, cisplatin/gemcitabine/necitumumab, cisplatin/vinorelbine, etoposide, irinotecan, and vinorelbine. For patients with squamous cell NSCLC, panel members deleted carboplatin/etoposide, carboplatin/vinorelbine, cisplatin/gemcitabine/necitumumab, cisplatin/vinorelbine, etoposide, irinotecan, and vinorelbine.

The NCCN NSCLC Panel recently voted unanimously to delete the necitumumab/cisplatin/gemcitabine regimen from the NCCN Guidelines for patients with metastatic squamous cell NSCLC. This decision reflects the fact that the NCCN NSCLC Panel feels the addition of necitumumab to the regimen is not beneficial based on toxicity, cost, and limited improvement in efficacy when compared with cisplatin/gemcitabine. A phase 3 randomized trial only showed a slight improvement in overall survival (11.5 months [95% CI, 10.4–12.6] vs. 9.9 months [95% CI, 8.9–11.1]).650 The stratified HR was only 0.84 (95% CI, 0.74–0.96; P = .01). In addition, there were more grade 3 or higher adverse events in patients receiving the necitumumab regimen (388 [72%] of 538 patients) than in patients receiving only the gemcitabine/cisplatin (333 [62%] of 541). Although it has been suggested that adding necitumumab to cisplatin/gemcitabine adds value and is cost-effective, the NCCN NSCLC Panel does not agree.651 Many oncologists use pemetrexed-based regimens for adenocarcinomas (if patients are not candidates for targeted therapy or immunotherapy), because taxane-based regimens are associated with more toxicity (eg, neurotoxicity).252,652 There are no agents for the prevention of peripheral neuropathy, and few agents are useful for treatment.653 The POINTBREAK trial showed that carboplatin/pemetrexed/bevacizumab is a reasonable option and confirmed that taxane-based regimens are more toxic than pemetrexed-based regimens.654 The POINTBREAK trial also showed that both regimens are similar in regard to overall survival rates; therefore, oncologists may return to using taxane-based regimens, which are well established. A retrospective cohort study suggests that the addition of bevacizumab (to carboplatin/paclitaxel) does not increase survival in older patients (≥65 years) with advanced nonsquamous NSCLC.655 However,
another retrospective cohort study reported increased survival in older patients.656 A combined analysis of the ECOG 4599 and POINTBREAK trials found a survival benefit with the addition of bevacizumab (to carboplatin/paclitaxel) in patients younger than 75 years but no benefit in those older than 75 years.657

For patients with advanced NSCLC who have a PS of 2, platinum-based combinations and a few single-agent chemotherapy agents are recommended in the NCCN Guidelines; cisplatin-based regimens are not recommended in this setting.658 For nonsquamous NSCLC or NSCLC NOS, single-agent chemotherapy includes gemcitabine, pemetrexed, or taxanes; combination chemotherapy regimens include carboplatin/paclitaxel or carboplatin/pemetrexed.659-661 Patients with a PS of 2 are often just treated with single-agent chemotherapy because of concerns about toxicity.662 Results from a trial reported that treatment with carboplatin/pemetrexed increased median overall survival when compared with pemetrexed alone (9.3 vs. 5.3 months, \( P = .001 \)) in patients with a PS of 2; however, 4 treatment-related deaths occurred in the carboplatin/pemetrexed arm.659,663 The NCCN NSCLC Panel recently deleted etoposide, irinotecan, and vinorelbine from the list of recommended single-agent chemotherapy for patients with all histologies because these agents are rarely used in the United States.

Phase 3 randomized trials have shown that many of the platinum-doublet combinations yield similar objective response rates and survival.664,665 The platinum-doublet regimens differ slightly for toxicity, convenience, and cost; thus, clinicians can individualize therapy for their patients.649,666-668 Other carboplatin-based regimens include gemcitabine/carboplatin, docetaxel/carboplatin, and pemetrexed/carboplatin;644,669-671 non–platinum-based regimens such as gemcitabine/vinorelbine and gemcitabine/docetaxel are also options.672-675 In spite of the development of new chemotherapy regimens, the prognosis for advanced inoperable lung cancer remains poor.

Note that albumin-bound paclitaxel (also known as nab-paclitaxel) can be substituted for paclitaxel or docetaxel for patients: 1) who have experienced hypersensitivity reactions after receiving paclitaxel or docetaxel despite premedication; or 2) in whom premedications (ie, dexamethasone, H2 blockers, H1 blockers) to prevent hypersensitivity are contraindicated.676,677 A phase 3 randomized trial reported that an albumin-bound paclitaxel/carboplatin regimen is associated with less neurotoxicity and improved response rate, when compared with the control arm of paclitaxel/carboplatin, in patients with advanced NSCLC.678 The FDA has approved albumin-bound paclitaxel/carboplatin for patients with locally advanced or metastatic NSCLC who are not candidates for curative surgery or RT. Based on the trial and the FDA approval, the NCCN NSCLC Panel recommends an albumin-bound paclitaxel/carboplatin regimen as initial cytotoxic therapy for patients with advanced NSCLC and good PS.

**Targeted Therapies**

Specific targeted therapies are available for the treatment of advanced NSCLC.146,679,680 Afatinib, alectinib, brigatinib, ceritinib, crizotinib, erlotinib, gefitinib, osimertinib, dacomitinib, dabrafenib, and trametinib are oral TKIs. Bevacizumab and ramucirumab are recombinant monoclonal antibodies that target vascular endothelial growth factor (VEGF) or VEGF receptor, respectively. Cetuximab is a monoclonal antibody that targets EGFR. Erlotinib, gefitinib, afatinib, and dacomitinib inhibit EGFR sensitizing mutations; osimertinib inhibits both EGFR sensitizing mutations and T790M. Crizotinib inhibits ALK rearrangements, ROS1 rearrangements, and MET (ie, high-level MET amplification, METex14 mutation). Ceritinib inhibits ALK rearrangements and IGF-1 receptor. Alectinib inhibits ALK and RET rearrangements. Brigatinib inhibits various ALK rearrangements.
and other targets.\textsuperscript{681} Dabrafenib/trametinib inhibits \textit{BRAF} V600E mutations; trametinib also inhibits MEK; both agents inhibit different kinases in the RAS/RAF/MEK/ERK pathway.\textsuperscript{154,155} Other targeted therapies are being developed (see \textit{Emerging Biomarkers to Identify Novel Therapies for Patients With Metastatic NSCLC} in the NCCN Guidelines for NSCLC).

\textbf{VEGF or VEGF Receptor Inhibitors}

\textbf{Bevacizumab}

Bevacizumab is a recombinant monoclonal antibody that targets VEGF. In 2006, the FDA approved bevacizumab for patients with unresectable, locally advanced, recurrent, or metastatic nonsquamous NSCLC.\textsuperscript{682} The ECOG recommends bevacizumab in combination with paclitaxel/carboplatin for select patients with advanced nonsquamous NSCLC based on the results of phase 2 to 3 clinical trials (ECOG 4599).\textsuperscript{251} To receive treatment with bevacizumab and chemotherapy, patients must meet the following criteria: nonsquamous NSCLC and no recent history of hemoptysis. Any regimen with a high risk for thrombocytopenia—and, therefore, possible bleeding—should be used with caution when combined with bevacizumab. Bevacizumab in combination with chemotherapy (ie, carboplatin/paclitaxel, carboplatin/pemetrexed, cisplatin/pemetrexed) is a recommended option for patients with a PS 0 to 1, nonsquamous NSCLC or NSCLC NOS, negative or unknown test results for \textit{ALK} rearrangements or sensitizing \textit{EGFR} mutations, PD-L1 expression less than 1% or unknown, and contraindications to immunotherapy (see \textit{Sensitizing EGFR Mutation Positive/First-Line Therapy or ALK Positive/First-Line Therapy} in the NCCN Guidelines for NSCLC). Bevacizumab in combination with a PD-L1 inhibitor plus chemotherapy (eg, atezolizumab/carboplatin/paclitaxel/bevacizumab) is a recommended option (category 1) regardless of PD-L1 expression for patients with PS 0 to 1, nonsquamous NSCLC or NSCLC NOS, negative or unknown test results for \textit{ALK} rearrangements or sensitizing \textit{EGFR} mutations, and no contraindications to immunotherapy or bevacizumab. However, bevacizumab is not recommended for patients with squamous cell NSCLC.

\textbf{Ramucirumab}

Ramucirumab is a recombinant monoclonal antibody that targets VEGF receptor. A phase 3 randomized trial (REVEL) assessed ramucirumab/docetaxel versus docetaxel alone in patients with metastatic NSCLC that had progressed.\textsuperscript{683} The median overall survival was reported to be slightly increased with ramucirumab/docetaxel versus docetaxel alone (10.5 vs. 9.1 months; HR, 0.86, 95\% CI, 0.75–0.98; \textit{P} < .023). Ramucirumab in combination with docetaxel is approved by the FDA for patients with metastatic NSCLC with disease progression on or after platinum-based chemotherapy.\textsuperscript{684} The NCCN NSCLC Panel added ramucirumab/docetaxel (category 2A) as an option for subsequent therapy for metastatic NSCLC that has progressed after first-line chemotherapy based on the phase 3 randomized trial and the FDA approval.\textsuperscript{683,684} Some panel members feel that the data are statistically significant but not clinically relevant. More than 70\% of patients had grade 3 or higher adverse events in both groups (79\% for ramucirumab/docetaxel vs. 71\% for docetaxel alone). Adverse events of special concern with ramucirumab/docetaxel therapy include risk for severe hemorrhage, grade 3 to 4 gastrointestinal bleeding, gastrointestinal perforation or fistula, impaired wound healing, and poorly controlled hypertension. There were 16 deaths from grade 3 or worse pulmonary hemorrhage and other adverse events in the REVEL trial: 8 deaths in the ramucirumab/docetaxel arm and 8 deaths in the docetaxel alone arm.
**Oral TKIs**

**Erlotinib and Gefitinib**

Erlotinib and gefitinib are oral TKIs that inhibit sensitizing EGFR mutations. In a phase 3 randomized trial (IPASS), patients with sensitizing EGFR mutations who received gefitinib had increased PFS (24.9% vs. 6.7%), response rate (71.2% vs. 47.3%), and quality of life with fewer side effects (eg, neutropenia) when compared with those receiving chemotherapy (carboplatin/paclitaxel). Updated results from the IPASS study showed that overall survival was similar in patients receiving gefitinib or chemotherapy regardless of sensitizing EGFR mutation status. These results probably occurred because patients who had been assigned to first-line chemotherapy were able to receive TKIs as subsequent therapy if they were found to have sensitizing EGFR mutations. A phase 3 randomized trial (EURTAC) in European patients with metastatic NSCLC and sensitizing EGFR mutations showed increased PFS and response rate for those receiving erlotinib when compared with chemotherapy. For erlotinib, the median PFS was 9.7 months (95% CI, 8.4–12.3) compared with 5.2 months (95% CI, 4.5–5.8) for chemotherapy (HR, 0.37; 95% CI, 0.25–0.54; P < .0001). Fewer patients receiving erlotinib had severe adverse events or died when compared with those receiving chemotherapy. The FDA has approved the use of erlotinib as first-line therapy in patients with sensitizing EGFR mutations. Previously, erlotinib was commonly used in the United States in patients with sensitizing EGFR mutations because of restrictions on the use of gefitinib. However, gefitinib was re-approved by the FDA based on a phase 4 study and is available in the United States. The NCCN NSCLC Panel recommends erlotinib and gefitinib (category 1) as first-line therapy in patients with advanced, recurrent, or metastatic nonsquamous NSCLC who have known active sensitizing EGFR mutations (regardless of their PS) based on these trials and FDA approvals (see *Sensitizing EGFR Mutation Positive* in the NCCN Guidelines for NSCLC).

EGFR TKIs are recommended in patients with metastatic NSCLC and sensitizing EGFR mutations, because quality of life is improved when compared with chemotherapy. Erlotinib and gefitinib are orally active TKIs that are very well tolerated by most patients. An analysis of 5 clinical trials in patients, mainly from the Western hemisphere, (n = 223) with advanced NSCLC (stage IIIB or IV) found that those with sensitizing EGFR mutations who received TKIs had a 67% response rate and an overall survival of about 24 months. The TORCH trial suggested that EGFR mutation testing should be done in patients with advanced nonsquamous NSCLC. Survival was increased in patients with wild-type EGFR who received first-line chemotherapy compared with those who received erlotinib first followed by subsequent chemotherapy (11.6 vs. 8.7 months). The OPTIMAL trial reported that PFS was increased in patients with sensitizing EGFR mutations who received erlotinib. ASCO recommends that patients be tested for EGFR mutations. The ESMO Guidelines specify that only patients with nonsquamous NSCLC (eg, adenocarcinoma) be assessed for EGFR mutations. Patients with pure squamous cell carcinoma are unlikely to have sensitizing EGFR mutations; those with adenosquamous carcinoma may have mutations. An updated study (CALGB 30406) compared erlotinib alone versus erlotinib/carboplatin/paclitaxel as first-line therapy in patients (mainly Caucasian) with advanced NSCLC. The data showed that erlotinib alone was associated with fewer side effects in patients with sensitizing EGFR mutations when compared with erlotinib/chemotherapy. Thus, it is appropriate to interrupt or complete planned chemotherapy and switch to EGFR TKI therapy in patients found to have sensitizing EGFR mutations during chemotherapy (see *EGFR Mutation Positive/First-Line Therapy* in the NCCN Guidelines for NSCLC). The NCCN Guidelines do not
recommend adding EGFR TKIs to current chemotherapy based on this CALGB study. EGFR TKIs may be continued in patients who have progressed if patients do not have multiple systemic symptomatic lesions (see **Continuation of Targeted Therapy After Progression on Initial Therapy** in this Discussion).

A phase 3 trial (WJOG 5108L) assessed gefitinib versus erlotinib for patients with advanced lung cancer who had been previously treated with chemotherapy; most patients (72%) were positive for EGFR mutations. The median PFS for gefitinib versus erlotinib was 8.3 and 10.0 months, respectively, in patients positive for EGFR mutations (HR, 1.093; 95% CI, 0.879–1.358; P = .424). The main grade 3 or 4 toxicities included rash (gefitinib: 2.2% vs. erlotinib: 18.1%) and increases in alanine aminotransferase (ALT)/aspartate aminotransferase (AST) levels (gefitinib: 6.1%/13.0% vs. erlotinib: 2.2%/3.3%).

**Afatinib**

Afatinib is a second-generation oral TKI that irreversibly inhibits the ErbB/HER family of receptors including EGFR and ERBB2. A randomized phase 3 trial reported that first-line therapy with afatinib improved PFS when compared with cisplatin/pemetrexed in patients with metastatic adenocarcinoma who have sensitizing EGFR mutations (11.1 vs. 6.9 months, P = .001). The FDA has approved afatinib for first-line treatment of patients with metastatic NSCLC who have sensitizing EGFR mutations. Based on this phase 3 randomized trial and the FDA approval, the NCCN NSCLC Panel recommends afatinib for first-line therapy (category 1) in patients with metastatic nonsquamous NSCLC who have sensitizing EGFR mutations (see the NCCN Guidelines for NSCLC). Afatinib may also be continued in patients who have progressed if patients do not have multiple systemic symptomatic lesions (see **Continuation of Targeted Therapy After Progression on Initial Therapy** in this Discussion).

However, afatinib is not recommended as subsequent therapy based on a phase 3 randomized trial [see **Second-Line and Beyond (Subsequent) Systemic Therapy** in this Discussion].

A phase 2B trial assessed afatinib compared with gefitinib for first-line therapy in patients with metastatic adenocarcinoma and sensitizing EGFR mutations. The PFS was essentially the same in patients receiving afatinib when compared with those receiving gefitinib (median PFS, 11.0 months [95% CI, 10.6–12.9] with afatinib vs. 10.9 months [9.1–11.5] with gefitinib; HR, 0.73 [95% CI, 0.57–0.95]; P = .017). These slight PFS differences are not clinically relevant and the NCCN Guidelines do not state that one EGFR TKI is more efficacious than another (see the NCCN Guidelines With Evidence Blocks™ for NSCLC, available at [www.NCCN.org](http://www.NCCN.org)).

Overall survival data are not yet available. Patients receiving afatinib had more serious treatment-related side effects when compared with those receiving gefitinib (11% [17/160] for afatinib vs. 4% [7/159] for gefitinib). One patient receiving gefitinib died from treatment-related hepatic and renal failure; other deaths were not considered to be related to treatment (9% vs. 6% [15/160 vs. 10/159]). More patients receiving afatinib had diarrhea (13% vs. 1%), whereas more patients receiving gefitinib had elevations in liver enzyme levels (0% vs. 9%). Afatinib is rated as slightly less safe than erlotinib or gefitinib (ie, a rating of 3 for afatinib vs. 4 for erlotinib and gefitinib) (see the NCCN Guidelines With Evidence Blocks™ for NSCLC, available at [www.NCCN.org](http://www.NCCN.org)).

**Osimertinib**

Osimertinib (AZD9291) is an oral TKI that inhibits both EGFR sensitizing mutations and T790M. EGFR T790M is a mutation associated with acquired resistance to first-line therapy with EGFR TKI therapy and has been reported in about 60% of patients with disease progression after initial response to sensitizing EGFR TKI therapy. Most patients
with sensitizing \textit{EGFR} mutations and metastatic NSCLC typically progress after about 9.7 to 13 months of therapy with erlotinib, gefitinib, or afatinib.\cite{199,206-208} Data show that patients receiving osimertinib as first-line therapy have PFS of about 19 months.\cite{704,705}

\textbf{First-Line Therapy}

A recent phase 3 trial (FLAURA) assessed first-line therapy with osimertinib compared with either erlotinib or gefitinib in patients with advanced or metastatic NSCLC and \textit{EGFR} mutations regardless of T790M status.\cite{704-706} Data show that osimertinib improved PFS (18.9 months [95% CI, 15.2–21.4]) when compared with either erlotinib or gefitinib (10.2 months [95% CI, 9.6–11.1]; HR, 0.46; 95% CI, 0.37–0.57; \(P < .001\))). The median duration of response was longer with osimertinib when compared with erlotinib or gefitinib (median, 17.2 vs. 8.5 months). Only 6% (17/279) of patients receiving osimertinib had CNS progression events when compared with 15% (42/277) of those receiving erlotinib or gefitinib. Grade 3 or higher adverse events were reported in 34% (94/279) of patients receiving osimertinib and 45% (124/277) of patients receiving erlotinib or gefitinib.

The NCCN NSCLC Panel recommends (category 1) osimertinib as a preferred first-line therapy option for patients with advanced or metastatic NSCLC who have sensitizing \textit{EGFR} mutations based on the phase 3 trial.\cite{704} For the 2019 update (Version 1), the panel voted that osimertinib is the preferred \textit{EGFR} TKI in this setting based on clinical trial data.\cite{704} For patients with sensitizing \textit{EGFR} mutations who progress during or after first-line therapy with osimertinib, recommended subsequent therapy depends on whether the progression is asymptomatic or symptomatic and includes: 1) considering local therapy; 2) continuing osimertinib; or 3) a first-line systemic therapy regimen for either nonsquamous or squamous cell NSCLC (such as cisplatin/pemetrexed or cisplatin/gemcitabine, respectively). There are no data to support using erlotinib, gefitinib, afatinib, or dacomitinib after progression on first-line therapy with osimertinib.

\textbf{Subsequent Therapy}

A recent phase 3 randomized trial assessed osimertinib versus platinum-pemetrexed chemotherapy in patients with \textit{EGFR} T790M-positive metastatic NSCLC who had progressed on first-line erlotinib, gefitinib, or afatinib. Data show that PFS was increased with osimertinib when compared with chemotherapy (10.1 vs. 4.4 months; HR, 0.30; 95% CI, 0.23–0.41; \(P < .001\)).\cite{208} PFS was also increased in patients with CNS metastases who received osimertinib (8.5 vs. 4.2 months; HR, 0.32; 95% CI, 0.21–0.49). In addition, the objective response rate was improved with osimertinib (71%; 95% CI, 65%–76%) when compared with chemotherapy (31%; 95% CI, 24%–40%) (odds ratio for objective response, 5.39; 95% CI, 3.47–8.48; \(P < .001\)). The disease control rate is about 93% with osimertinib (95% CI, 90%–96%) and about 74% with chemotherapy (95% CI, 66%–81%). Patients receiving osimertinib had fewer grade 3 or higher adverse events when compared with those receiving chemotherapy (23% vs. 47% [63/279 vs. 64/136]). There were 4 fatal events with osimertinib (respiratory failure [2], pneumonitis, ischemic stroke) and one with chemotherapy (hypovolemic shock).

The FDA has approved osimertinib for patients with metastatic \textit{EGFR} T790M-positive NSCLC, as detected by an FDA-approved test, who have progressed on or after first-line therapy with erlotinib, gefitinib, or afatinib. Based on a phase 3 randomized trial and FDA approval, the NCCN NSCLC Panel recommends osimertinib (category 1) as subsequent therapy for patients with metastatic \textit{EGFR} T790M-positive NSCLC who have progressed on erlotinib, gefitinib, or afatinib [see Second-Line and Beyond (Subsequent) Systemic Therapy in this Discussion].\cite{208} T790M can be assessed using an FDA-approved test or other validated laboratory test done in a CLIA-approved laboratory. Data suggest that plasma genotyping
(also known as plasma testing or liquid biopsy) may be considered at progression instead of tissue biopsy to detect whether patients have T790M; however, if plasma testing is negative, then tissue biopsy is recommended.\textsuperscript{707-709} The NCCN NSCLC Panel also recommends osimertinib (category 1) for patients with T790M who have progression with symptomatic brain metastases based on data showing an improvement.\textsuperscript{208,710-713}

Several studies suggest that pulse erlotinib is beneficial for patients with EGFR mutations who have progressive leptomeningeal disease.\textsuperscript{714-716} In one study of high-dose erlotinib, neurologic symptoms and PS improved in 50\% (6/12) and 33\% (4/12) of patients, respectively; median survival was 6.2 months (95\% CI, 2.5–8.5).\textsuperscript{716} Preliminary data from a recent study (BLOOM) suggest that osimertinib is beneficial for patients with EGFR mutations (regardless of T790M status) who have progressive leptomeningeal disease.\textsuperscript{717} In this study (n = 32), 23 patients receiving osimertinib (160 mg once daily) had brain imaging assessment; 10 had radiologic improvement and 13 had stable disease. At a 12-week neurologic assessment, 88\% (7/8) of symptomatic patients improved and one had stable disease. Of 15 asymptomatic patients, 87\% (13/15) remained asymptomatic.\textsuperscript{717} Based on these studies, the NCCN NSCLC Panel feels that osimertinib (regardless of T790M status) or pulse erlotinib can be considered for patients with EGFR mutations who have progressive leptomeningeal disease.\textsuperscript{718,719} Data also suggest that afatinib may be beneficial in patients with EGFR mutations who have progressive leptomeningeal disease.\textsuperscript{718,719}

Dacomitinib
Like afatinib, dacomitinib is a second-generation oral TKI that irreversibly inhibits ErbB/HER receptors including EGFR, HER1, HER2, and HER4. A recent phase 3 randomized trial (ARCHER 1050) compared dacomitinib versus gefitinib as first-line therapy for patients with sensitizing EGFR-positive metastatic NSCLC\textsuperscript{720} Patients with brain metastases were not eligible for enrollment. PFS was increased in patients receiving dacomitinib (14.7 months [95\% CI, 11.1–16.6]) compared with those receiving gefitinib (9.2 months [95\% CI, 9.1–11.0]). Serious adverse events related to treatment were reported in 21 (9\%) patients given dacomitinib and in 10 (4\%) patients given gefitinib. Treatment-related deaths included 2 patients in the dacomitinib group (one related to untreated diarrhea and one to untreated cholelithiasis/liver disease) and one patient in the gefitinib group (related to sigmoid colon diverticulitis/rupture complicated by pneumonia). For the 2019 update (Version 1), the NCCN NSCLC Panel voted to recommend dacomitinib (category 1) as a first-line treatment option for patients with sensitizing EGFR-positive metastatic NSCLC based on these clinical trial data and the FDA approval.

Crizotinib
Crizotinib inhibits ALK rearrangements, ROS1 rearrangements, and some MET tyrosine kinases (high-level \textit{MET} amplification or \textit{METex14} mutation); it is approved by the FDA for patients with metastatic NSCLC who have ALK gene rearrangements (ie, ALK-positive disease) or ROS1 rearrangements.\textsuperscript{138,721-727} The NCCN NSCLC Panel recommends 4 agents for patients with ALK-positive disease—alectinib, crizotinib, brigatinib, and ceritinib—and all are category 1 based on phase 3 randomized trials and FDA approvals (see the \textit{Alectinib} and \textit{Ceritinib} and \textit{ALK Rearrangements} in this Discussion and the NCCN Guidelines for NSCLC). The NCCN NSCLC Panel voted that alectinib (category 1) is the preferred agent for first-line therapy for patients with metastatic NSCLC who are positive for ALK gene rearrangements (see \textit{Alectinib} in this Discussion). The NCCN NSCLC Panel recommends 2 agents for patients with ROS1 rearrangements—crizotinib (preferred) and ceritinib—based on trial data and FDA approvals (see \textit{Ceritinib} in this Discussion).
ALK Rearrangements

Crizotinib yields very high response rates (>60%) when used in patients with advanced NSCLC who have ALK rearrangements, including those with brain metastases.\(^ {95,248,723,728,729}\) Patients whose disease responds to crizotinib may have rapid improvement in symptoms; median time to progression on crizotinib is about 7 months to 1 year.\(^ {730,731}\) Crizotinib has relatively few side effects (eg, eye disorders, edema, transient changes in renal function).\(^ {248,732,733}\) However, some patients have had pneumonitis; crizotinib should be discontinued in these patients.\(^ {725}\) Patients who do not tolerate crizotinib may be switched to alectinib, ceritinib, or brigatinib (if not previously given) unless an adverse side effect requiring discontinuation has occurred (eg, pneumonitis). Randomized phase 3 trials have compared crizotinib with first-line therapy (PROFILE 1014) and with subsequent chemotherapy (PROFILE 1007).\(^ {7,723,734}\) First-line therapy with crizotinib improved PFS, response rate (74% vs. 45%; \(P < .001\)), lung cancer symptoms, and quality of life when compared with chemotherapy (pemetrexed with either cisplatin or carboplatin).\(^ {723}\)

The NCCN NSCLC Panel recommends first-line therapy with crizotinib (category 1) based on this phase 3 trial and the FDA approval. Crizotinib may also be continued for patients with ALK rearrangements who have progressed, depending on the type of progression.\(^ {724}\) For the 2019 update (Version 1), the NCCN NSCLC Panel deleted the option to continue crizotinib for patients with brain metastases who had progressed after first-line therapy with crizotinib; the other ALK inhibitors are recommended options in this setting because they have better CNS response rates (ie, ceritinib, alectinib, brigatinib).\(^ {735-738}\) The NCCN NSCLC Panel also deleted the recommendation to consider switching ALK inhibitors before considering whole brain RT for patients with ALK rearrangements and brain metastases in the 2019 update (Version 1). Subsequent therapy with crizotinib improved PFS (7.7 vs. 3.0 months; \(P < .001\)) and response rate (65% vs. 20%; \(P < .001\)) when compared with single-agent therapy (either docetaxel or pemetrexed) in patients with ALK-positive NSCLC who had progressed after first-line chemotherapy.\(^ {724}\) Based on this trial, crizotinib is recommended as subsequent therapy in patients with ALK-positive disease.

ROS1 Rearrangements

Crizotinib is also very effective for patients with ROS1 rearrangements with response rates of about 70% to 80% including complete responses (see other section on ROS1 Rearrangements in this Discussion).\(^ {138,139,257,258}\) A recent phase 2 trial assessed crizotinib in East Asian patients (n=127) with ROS1-positive advanced NSCLC who had received 3 or fewer lines of therapy. The overall response rate was 72% (95% CI, 63%–79%) with 17 complete responses; the median duration of response was 19.7 months (95% CI, 14.1–not reached). The median PFS was 15.9 months (95% CI, 12.9–24.0).\(^ {257}\) In 50 patients with advanced NSCLC who were positive for ROS1 rearrangements, crizotinib yielded an objective response rate of 72% (95% CI, 58%–84%); there were 3 complete responses and 33 partial responses.\(^ {139}\) The median duration of response was 17.6 months (95% CI, 14.5–not reached), and the median PFS was 19.2 months (95% CI, 14.4–not reached). The safety profile of crizotinib was similar to the safety seen in patients with ALK-rearranged NSCLC. A retrospective European study in patients (n = 30 evaluable) with stage IV NSCLC and ROS1 rearrangements also assessed crizotinib.\(^ {138}\) There were 5 complete responses (overall response rate, 80%; disease control rate, 86.7%). The median PFS was 9.1 months. Many patients (n = 26) received pemetrexed (either alone or in combination with platinum and either before or after crizotinib) and had a response rate of 57.7% and a median PFS of 7.2 months.

The NCCN NSCLC Panel recommends ROS1 testing based on data showing the efficacy of crizotinib for patients with ROS1 rearrangements.
and on the FDA approval (see Principles of Molecular and Biomarker Analysis in the NCCN Guidelines for NSCLC). The NCCN NSCLC Panel voted that crizotinib is the preferred agent for first-line therapy in patients with ROS1 rearrangements, when compared with ceritinib, based on the trial data and the FDA approval (see Ceritinib in this Discussion). Alectinib or brigatinib is not recommended in patients with ROS1 rearrangements whose disease becomes resistant to crizotinib or ceritinib.

Ceritinib
Ceritinib is an oral TKI that inhibits ALK and ROS1 rearrangements.

ALK Rearrangements
A recent phase 3 trial assessed ceritinib versus platinum-based chemotherapy as first-line therapy for patients with ALK-positive metastatic NSCLC. PFS was improved when using ceritinib when compared with platinum-based chemotherapy; the median PFS was 16.6 months (95% CI, 12.6–27.2) for ceritinib and 8.1 months (95% CI, 5.8–11.1) for chemotherapy (HR, 0.55 [95% CI, 0.42–0.73]; P < .00001). For ceritinib, common adverse events included diarrhea (85% [160/189] of patients), nausea (69% [130/189]), vomiting (66% [125/189]), and an increase in ALT (60% [114/189]). For chemotherapy, common adverse events included nausea (55% [97/175 patients]), vomiting (36% [63/175]), and anemia (35% [62/175]). The NCCN NSCLC Panel recommends (category 1) ceritinib as first-line therapy for patients with ALK-positive metastatic NSCLC based on this phase 3 trial and FDA approval. However, the NCCN NSCLC Panel voted that alectinib (category 1) is the preferred agent for first-line therapy for patients with metastatic NSCLC who are positive for ALK gene rearrangements (see Alectinib in this Discussion).

Ceritinib is approved by the FDA for patients with ALK-positive metastatic NSCLC who have progressed on or are intolerant to crizotinib. The approval is based on an expanded phase 1 study (ASCEND-1) showing overall response rates of 56% to ceritinib in patients (92/163) who had previously received crizotinib; the median duration of response was 8.3 months (6.8–9.7). Common grade 3 to 4 adverse events included increased ALT (73 [30%] patients) and increased AST (25 [10%]). Some patients with CNS lesions responded to ceritinib. Based on the study and the FDA approval, the NCCN NSCLC Panel recommends ceritinib as subsequent therapy for patients with ALK-positive NSCLC who have progressed after crizotinib. Patients who do not tolerate crizotinib may be switched to alectinib, ceritinib, or brigatinib, if not previously given.

A recent phase 3 trial (ASCEND-5) assessed subsequent therapy with ceritinib versus chemotherapy (with pemetrexed or docetaxel) in patients with advanced ALK-positive NSCLC who had previously received at least 2 or more treatments (including chemotherapy and crizotinib) and had progressed. Patients receiving ceritinib had a significant improvement in median PFS when compared with chemotherapy (5.4 months [95% CI, 4.1–6.9] for ceritinib vs. 1.6 months [1.4–2.8] for chemotherapy; HR, 0.49 [0.36–0.67]; P < .0001). Serious adverse events were reported in 43% (49/115) of patients receiving ceritinib versus 32% (36/113) of those receiving chemotherapy. A phase 2 trial (ASCEND-2) assessed ceritinib in patients who had previously received at least 2 or more treatments, had progressed on crizotinib, and had brain metastases. The overall response rate was 38%; the duration of response was 9.7 months (95% CI, 7.1–11.1). The intracranial overall response rate was 45.0% (95% CI, 23.1%–68.5%).

ROS1 Rearrangements
A recent phase 2 trial assessed ceritinib as first-line therapy in patients (n = 28 evaluable) with NSCLC and ROS1 rearrangements. One complete response and 19 partial responses (overall response rate, 62% [95% CI, 45%–77%]) were reported in patients receiving ceritinib. PFS was 19.3
months (95% CI, 1–37) for crizotinib-naïve patients and 9.3 months (95% CI, 0–22) for all patients. The median overall survival was 24 months (95% CI, 5–43). The NCCN NSCLC Panel recommends ceritinib (category 2A) for patients with ROS1-positive advanced NSCLC based on this trial. However, the NCCN NSCLC Panel voted that crizotinib is the preferred agent for first-line therapy for patients with advanced NSCLC and ROS1 rearrangements for the 2018 update (Version 1) (see Crizotinib in this Discussion).

**Alectinib**
Alectinib is an oral TKI that inhibits ALK and RET rearrangements but not MET or ROS1 rearrangements.

**First-Line Therapy**
The ALEX phase 3 trial assessed first-line therapy with alectinib versus crizotinib in 303 patients with ALK-positive advanced NSCLC including those with asymptomatic CNS disease. Disease progression or death occurred in fewer patients receiving alectinib (41% [62/152]; median follow-up of 18.6 months) when compared with crizotinib (68% [102/151]; median follow-up of 17.6 months). The HR was 0.47 (95% CI, 0.34–0.65; \( P < .001 \)) for disease progression or death. PFS was significantly increased with alectinib (68.4% [95% CI, 61.0%–75.9%]) versus crizotinib (48.7% [95% CI, 40.4%–56.9%]). The median PFS was not reached for alectinib (95% CI, 17.7–not reached) when compared with crizotinib at 11.1 months (95% CI, 9.1–13.1). Fewer patients receiving alectinib had CNS progression (12% [18/152]) versus crizotinib (45% [68/151]). Response rates were 83% (126/152) in the alectinib group versus 75% (114/151) in the crizotinib group (\( P = .09 \)). Patients receiving alectinib had fewer grade 3 to 5 adverse events when compared with crizotinib (41% [63/152] vs. 50% [75/151], respectively) even though patients received alectinib for a longer duration than crizotinib (median, 17.9 vs. 10.7 months). There were also fewer deaths in the alectinib arm (3.3% [5/152]) versus the crizotinib arm (4.6% [7/151]); 2 treatment-related deaths were reported in the crizotinib arm and none in the alectinib arm.

The J-ALEX phase 3 randomized trial assessed first-line therapy with alectinib versus crizotinib in 207 Japanese patients with ALK-positive advanced NSCLC. The data showed that median PFS had not yet been reached with alectinib (95% CI, 20.3 months–not reached) versus 10.2 months (95% CI, 8.2–12.0) with crizotinib (HR, 0.34 [99.7% CI, 0.17–0.71], stratified log-rank \( P < .0001 \)). Grade 3 or 4 adverse events were less frequent with alectinib (26% [27/103]) when compared with crizotinib (52% [54/104]); adverse events did not lead to death in either group. Fewer patients stopped taking alectinib (9%) because of an adverse event when compared with crizotinib (20%).

The NCCN NSCLC Panel recommends alectinib as first-line therapy (category 1) for patients with ALK-positive metastatic NSCLC based on these two randomized phase 3 trials and recent FDA approval. Panel members voted that alectinib is the preferred agent for first-line therapy for patients with metastatic NSCLC who are positive for ALK gene rearrangements based on these trials. For the 2019 update (Version 1), the NCCN NSCLC Panel recommends that alectinib is also the preferred ALK inhibitor when an ALK rearrangement is discovered during first-line chemotherapy. Crizotinib, brigatinib, or ceritinib are also recommended (category 1) as first-line therapy options in patients with ALK-positive NSCLC (see Crizotinib and Ceritinib in this Discussion).

**Subsequent Therapy**
Alectinib is approved by the FDA for patients with ALK-positive metastatic NSCLC who have progressed on or are intolerant to crizotinib. The FDA approval is based on phase 2 trials showing overall response rates of 48% to 50% to alectinib in patients who had previously received crizotinib. In the larger trial (138 patients) by Ou et al, patients on alectinib had a
response rate of 50% (95% CI, 41%–59%), and median duration of response of 11.2 months (95% CI, 9.6–not reached). For CNS disease, the control rate was 83% (95% CI, 74%–91%) and the median duration of response was 10.3 months (95% CI, 7.6–11.2). Of 84 patients with baseline CNS metastases, 23 (27%) had a complete CNS response to alectinib. Of 23 patients with baseline CNS metastases and no previous brain RT, 10 (43%) had a complete CNS response to alectinib. Most adverse events were only grade 1 to 2 (constipation, fatigue, and peripheral edema); 4 patients (3%) had grade 3 dyspnea. One death due to intestinal perforation may have been related to alectinib. Based on these trials and the FDA approval, the NCCN NSCLC Panel recommends alectinib as subsequent therapy for patients with ALK-positive NSCLC who have progressed after crizotinib; patients who do not tolerate crizotinib may be switched to alectinib, ceritinib, or brigatinib (if not previously given).

**Brigatinib**
Brigatinib is an oral TKI that inhibits ALK rearrangements.

**First-Line Therapy**
A recent phase 3 trial assessed brigatinib versus crizotinib as first-line therapy for patients with ALK-positive metastatic NSCLC. PFS was increased in patients receiving brigatinib (67% [95% CI, 56%–75%]) versus those receiving crizotinib (43% [95% CI, 32%–53%]) (HR for disease progression or death, 0.49 [95% CI, 0.33–0.74]; \(P < .001\)). Intracranial response was also increased with brigatinib (78% [95% CI, 52%–94%]) versus crizotinib (29% [95% CI, 11%–52%]). For the 2019 update (Version 1), the NCCN NSCLC Panel voted to recommend brigatinib (category 1) as a first-line therapy option for patients with ALK-positive NSCLC based on this phase 3 trial.

**Subsequent Therapy**
Brigatinib is approved by the FDA for patients with ALK-positive metastatic NSCLC who have progressed on or are intolerant to crizotinib. The FDA approval is based on data from a phase 2 trial (ALTA) assessing 2 different doses of brigatinib: 90 mg (arm A) or 180 mg (arm B) every day. The overall response rates were 45% (97% CI, 34%–56%) and 54% (97% CI, 43%–65%) in arms A and B, respectively. Many patients had brain metastases (71% and 67%, respectively). The intracranial overall response rates were 42% (11/26) and 67% (12/18), respectively. Grade 3 or higher adverse events included hypertension (6% and 6%, respectively) and pneumonia (3% and 5%, respectively). Patients receiving brigatinib should be carefully monitored for respiratory symptoms, especially during the first week of treatment. The NCCN NSCLC Panel recommends brigatinib (category 2A) as subsequent therapy for patients with ALK-positive NSCLC who have progressed after crizotinib based on this trial and the FDA approval. Patients who do not tolerate crizotinib may be switched to alectinib, brigatinib, or ceritinib (if not previously given). A recent retrospective study (22 patients) assessed brigatinib in patients with alectinib-refractory advanced ALK-positive NSCLC. Objective responses occurred in 17% (3/18) of patients; 50% (9/18) of patients had stable disease.

**Lorlatinib**
Lorlatinib is an oral third-generation TKI that targets ALK and ROS1 tyrosine kinases and has good CNS penetration; it inhibits a broad range of ALK resistance mutations that develop after treatment with first- and second-generation ALK inhibitors.
Subsequent Therapy

Data show that lorlatinib is effective in select patients who have progressed after treatment with ALK inhibitors, including those with CNS metastases.\(^{245,246}\) A phase 2 trial assessed lorlatinib in patients with ALK-positive or ROS1-positive metastatic NSCLC who had progressed after ALK inhibitor therapy; many patients had asymptomatic CNS metastases.\(^{245}\) In patients who had received at least one previous ALK inhibitor, objective responses were achieved in 47% of patients (93/198; 95% CI, 39.9%–54.2%); there were 4 complete responses and 89 partial responses. In those with measurable baseline CNS lesions, an objective intracranial response was observed in 63% of patients (51/81; 95% CI, 51.5%–73.4%). Lorlatinib was effective in patients who had received up to 3 previous ALK inhibitors. Grade 3 to 4 adverse events included hypercholesterolemia and hypertriglyceridemia (43/275 [16%] for both). Serious treatment-related adverse events occurred in 7% of patients (19/275) including cognitive effects in 1% (2/275); the cognitive effects resulted in permanent discontinuation of lorlatinib. No treatment-related deaths were reported.

For the 2019 update (Version 2), the NCCN NSCLC Panel now recommends lorlatinib (category 2A) as a subsequent therapy option for select patients with ALK-positive NSCLC who have progressed after treatment with ALK inhibitors based on clinical trial data and FDA approval. The NCCN NSCLC Panel also recommends subsequent therapy with lorlatinib (category 2A) for select patients with ROS1-positive NSCLC who have progressed after treatment with crizotinib or ceritinib.

Dabrafenib and Trametinib

Dabrafenib and trametinib inhibit kinases in the RAS/RAF/MEK/ERK pathway.\(^{154,155}\) Dabrafenib inhibits BRAF harboring V600E mutations; trametinib inhibits MEK 1/2, which is downstream of BRAF signaling. The combination regimen of dabrafenib/trametinib is approved by the FDA for patients with BRAF V600E mutations and metastatic NSCLC.\(^{750}\)

A phase 2 trial assessed first-line combination therapy with dabrafenib/trametinib for 36 patients with metastatic NSCLC and BRAF V600E mutations.\(^{751}\) The overall response rate was 64% (23/36; 95% CI, 46%–79%); there were 2 complete responses. The median PFS was 10.9 months (95% CI, 7.0–16.6). Many patients (69% [25/36]) had one or more grade 3 or 4 adverse events. Serious adverse events included increased ALT (14% [5/36]), increased AST (8% [3/36]), pyrexia (11% [4/36]), and decreased ejection fraction (8% [3/36]).

A phase 2 study assessed the dabrafenib/trametinib regimen as subsequent therapy in 57 patients with advanced NSCLC and BRAF V600E mutations who had progressed on chemotherapy.\(^{154,752}\) Patients had a response rate of 63% (36/57) with dabrafenib/trametinib; however, considerable toxicity was reported. PFS was 9.7 months (6.9–19.6). Serious adverse events occurred in 56% (32/57) of patients, including pyrexia, anemia, confusional state, hemoptysis, hypercalcemia, and cutaneous squamous cell carcinoma. Grade 3 to 4 adverse events included neutropenia in 9% of patients (5/57), hyponatremia in 7% (4/57), and anemia in 5% (3/57). Four patients died during the study, but these deaths were not felt to be related to treatment (deaths were due to retroperitoneal hemorrhage, subarachnoid hemorrhage, respiratory distress, or severe disease progression). Preliminary data from an updated analysis of this phase 2 trial reported that patients receiving dabrafenib/trametinib had a median overall survival of 18.2 months (95% CI, 14.3–not reached).\(^{753}\)

The NCCN NSCLC Panel recommends combination therapy with dabrafenib/trametinib as first-line therapy for patients with metastatic NSCLC and BRAF V600E mutations based on these trials and the FDA approval.\(^{750,751,753}\) Chemotherapy regimens (with or without...
immunotherapy) are also recommended for patients with *BRAF* V600E mutations; the same initial systemic regimens used for patients with metastatic NSCLC may be used (eg, carboplatin/paclitaxel). Single-agent therapy with dabrafenib or vemurafenib is also an option for patients with *BRAF* V600E mutations who do not tolerate combination therapy with dabrafenib/trametinib.\textsuperscript{155,160,753} If patients with *BRAF* V600E mutations have not received dabrafenib/trametinib as first-line therapy and have progressed after first-line therapy chemotherapy regimens (with or without immunotherapy), then the NCCN NSCLC Panel recommends dabrafenib/trametinib as subsequent therapy.

**Larotrectinib**

*NTRK* gene fusions encode TRK fusion proteins that act as oncogenic drivers for various solid tumors, including lung, salivary gland, thyroid, and sarcoma (see *NTRK Gene Fusions* in this Discussion).\textsuperscript{267} Larotrectinib is an oral TKI that inhibits TRK across a diverse range of solid tumors in younger and older patients with unresectable or metastatic disease; thus, larotrectinib is referred to as an age- and tumor-agnostic therapy.\textsuperscript{267} A study in patients (n = 55) with *NTRK* gene–fusion positive disease showed that larotrectinib yielded an overall response rate of 75% (95% CI, 61%–85%).\textsuperscript{267} A recent update of this study showed that 90% of patients were still alive after 1 year, 18% of patients had a complete response, 69% of patients were still responding, and 58% of patients had not progressed.\textsuperscript{268} An additional 35 patients with *NTRK* gene fusion–positive disease had an overall response rate of 74%.\textsuperscript{268} Fewer than 3% of patients had adverse events of grade 3 to 4. For the 2019 update (Version 3), the NCCN NSCLC Panel recommends larotrectinib (category 2A) for patients with *NTRK* gene fusion–positive metastatic NSCLC based on these data and the recent FDA approval.\textsuperscript{267}

**EGFR Inhibitor**

**Cetuximab**

Cetuximab is a monoclonal antibody that targets EGFR. A large phase 3 randomized trial (FLEX) assessed cisplatin/vinorelbine with (or without) cetuximab for patients with advanced NSCLC; most patients had stage IV disease.\textsuperscript{754} Adding cetuximab was reported to slightly increase overall survival (11.3 vs. 10.1 months; HR for death, 0.87 [95% CI, 0.762–0.996]; \( P = .044 \)). Patients receiving cetuximab had increased grade 4 events versus control (62% vs. 52%, \( P < .01 \)); cetuximab was also associated with grade 2 acne-like rash.

The cetuximab/cisplatin/vinorelbine regimen is not recommended in the NCCN Guidelines. The benefits of this cetuximab-based regimen are very slight, it is a difficult regimen to administer, and patients have poorer tolerance for this regimen when compared with other regimens; for example, almost 40% of patients have grade 4 neutropenia.\textsuperscript{594} Patients may also have comorbid conditions that prevent them from receiving cisplatin such as poor kidney function. Cisplatin/vinorelbine with (or without) cetuximab is generally not used in the United States because of concerns about toxicity.\textsuperscript{594,615,754} Some oncologists feel that although the FLEX trial results were reported to be statistically significant, they were not clinically significant.\textsuperscript{594} The NCCN NSCLC Panel recently deleted the cisplatin/vinorelbine and carboplatin/vinorelbine regimens from the list of recommended cytotoxic therapy regimens for metastatic NSCLC with all histologies.

**Immune Checkpoint Inhibitors**

Human immune-checkpoint–inhibitor antibodies inhibit the PD-1 receptor or PD-L1, which improves antitumor immunity; PD-1 receptors are expressed on activated cytotoxic T cells.\textsuperscript{275-277} Immune checkpoint
inhibitors are associated with a delay in benefit when compared with targeted therapy or cytotoxic chemotherapy. The single-agent immunotherapy or combination immunotherapy/chemotherapy regimens are not recommended if patients have contraindications to immunotherapy (eg, active or previously documented autoimmune disease, current use of immunosuppressive agents, or presence of an oncogene that would predict lack of benefit). The following briefly summarizes the use of immune checkpoint inhibitors as first-line or subsequent therapy in select patients with NSCLC; detailed information, including clinical trial data, are provided in the following sections. The immune checkpoint inhibitors nivolumab and pembrolizumab inhibit PD-1 receptors;\textsuperscript{278,104} atezolizumab and durvalumab inhibit PD-L1.\textsuperscript{279,280} Single-agent pembrolizumab is recommended (category 1 preferred) as first-line therapy for patients with PD-L1 expression levels greater than 50% and with negative or unknown test results for \textit{EGFR} mutations and \textit{ALK} rearrangements.\textsuperscript{282} Combination therapy with pembrolizumab (or atezolizumab/bevacizumab)/chemotherapy is recommended (category 1) as a first-line therapy option for patients with negative or unknown test results for \textit{EGFR} mutations and \textit{ALK} rearrangements, regardless of PD-L1 expression levels. Durvalumab is recommended (category 1) as consolidation immunotherapy by the NCCN NSCLC Panel for patients with unresectable stage III NSCLC who have not progressed after definitive concurrent chemoradiation; appropriate use and clinical trial data for durvalumab are described in greater detail elsewhere (see \textit{Durvalumab} in this Discussion).\textsuperscript{279} Single-agent pembrolizumab is recommended (category 1 preferred) as subsequent therapy for select patients with metastatic NSCLC and PD-L1 levels greater than 1%; nivolumab or atezolizumab is recommended (category 1 preferred) as subsequent monotherapy for select patients with metastatic NSCLC regardless of PD-L1 levels (see \textit{Pembrolizumab, Nivolumab, and Atezolizumab} in this Discussion). Based on data in the second-line setting, PD-1 or PD-L1 inhibitor monotherapy appears to be less effective in patients with \textit{EGFR} mutations or \textit{ALK} rearrangements regardless of PD-L1 expression levels.\textsuperscript{275,278,286-288} Therefore, if patients have progressed on PD-1/PD-L1 inhibitor therapy (with or without chemotherapy), then switching to another PD-1/PD-L1 inhibitor is not routinely recommended. A small study suggests that single-agent pembrolizumab is not effective as first-line therapy in patients with metastatic NSCLC and \textit{EGFR} mutations, even those with PD-L1 levels more than 50%.\textsuperscript{289}

Checkpoint inhibitors are associated with unique immune-mediated adverse events that are not seen with traditional cytotoxic chemotherapy (eg, endocrine disorders); therefore, health care providers should be aware of the spectrum of potential immune-mediated adverse events, know how to manage the adverse events, and educate their patients about possible side effects (see the NCCN Guidelines for the Management of Immunotherapy-Related Toxicities, available at www.NCCN.org).\textsuperscript{755,756} Nivolumab, pembrolizumab, durvalumab, and atezolizumab should be discontinued for patients with severe or life-threatening pneumonitis and should be withheld or discontinued for other severe or life-threatening immune-mediated adverse events when indicated (see prescribing information). Pseudoprogression has been reported; therefore, traditional RECIST criteria may not be applicable.\textsuperscript{757}

\textbf{Nivolumab}

If patients have not previously received a PD-1/PD-L1 inhibitor, the NCCN NSCLC Panel recommends single-agent nivolumab (category 1 preferred) as subsequent therapy for patients with metastatic nonsquamous or squamous NSCLC who have progressed on or after first-line
chemotherapy based on data from two phase 3 randomized trials (CheckMate-057, CheckMate-017) and FDA approvals. The NCCN NSCLC Panel recommends nivolumab, atezolizumab, or pembrolizumab as preferred agents for subsequent therapy based on improved overall survival rates, longer duration of response, and fewer adverse events when compared with cytotoxic chemotherapy.

For patients with metastatic nonsquamous NSCLC, the category 1 recommendation for subsequent therapy with nivolumab is based on data from a phase 3 randomized trial (CheckMate-057) and FDA approval. For patients receiving nivolumab in the CheckMate-057 trial, median overall survival was 12.2 months compared with 9.4 months for docetaxel (HR, 0.73; 95% CI, 0.59–0.89; P = .002). The median duration of response was 17.2 months with nivolumab compared with 5.6 months for docetaxel. At 18 months, the overall survival rate was 39% (95% CI, 34%–45%) with nivolumab compared with 23% (95% CI, 19%–28%) with docetaxel. Fewer grade 3 to 5 adverse events were reported for nivolumab (10%) when compared with docetaxel (54%). Although many patients with metastatic nonsquamous NSCLC benefit from nivolumab, those whose tumors have PD-L1 staining of 1% to 10% or more have an overall survival of 17 to 19 months compared with 8 to 9 months for docetaxel. For patients who did not have PD-L1 expression, there was no difference in overall survival for nivolumab versus docetaxel; however, nivolumab was associated with a longer duration of response and fewer side effects.

To help clinicians determine which patients with nonsquamous NSCLC may benefit most from treatment with nivolumab, the FDA has approved a complementary diagnostic biomarker test to assess for PD-L1 protein expression. Testing for PD-L1 is not required for prescribing nivolumab but may provide useful information. Current or former smoking status correlated with the response rate to immune checkpoint inhibitors. Data suggest that mismatch repair deficiency is associated with response to immune checkpoint inhibitors.

The NCCN NSCLC Panel also recommends (category 1) nivolumab as subsequent therapy for patients with metastatic squamous cell NSCLC who have progressed on or after first-line chemotherapy based on data from a phase 3 randomized trial (CheckMate-017), and FDA approval. In the CheckMate-017 trial, the median overall survival was 9.2 months with nivolumab compared with 6.0 months for docetaxel. Patients had a response rate of 20% with nivolumab compared with 9% for docetaxel (P=.008). PD-L1 expression was not associated with response to nivolumab in patients with squamous cell NSCLC. There were fewer grade 3 to 4 adverse events with nivolumab (7%) when compared with docetaxel (55%). No patients died in the nivolumab arm versus 3 deaths in the docetaxel arm.

In a recent long-term analysis of both trials (CheckMate-057 and CheckMate-017), 2-year survival and durable responses were improved in patients with advanced NSCLC receiving nivolumab when compared with docetaxel. For patients with nonsquamous NSCLC, 2-year survival was 29% (95% CI, 24%–34%) with nivolumab versus 16% (95% CI, 12%–20%) with docetaxel. For those with squamous NSCLC, 2-year survival was 23% (95% CI, 16%–30%) with nivolumab versus 8% (95% CI, 4%–13%) with docetaxel. Fewer severe treatment-related adverse events were reported with nivolumab compared with docetaxel (grade 3–4, 10% vs. 55%).

Immune-related adverse events, such as pneumonitis, may occur with nivolumab. Intravenous high-dose corticosteroids should be administered based on the severity of the reaction for patients with immune-mediated adverse events. Nivolumab should be discontinued for patients with severe or life-threatening pneumonitis and should be withheld or discontinued for other severe or life-threatening
immune-mediated adverse events when indicated (see prescribing information).

A recent phase 3 randomized trial compared first-line nivolumab/ipilimumab, nivolumab monotherapy, and chemotherapy in patients with metastatic nonsquamous or squamous NSCLC who had high TMB levels (≥10 mutations/megabase), PS 0 to 1, and no EGFR mutations or ALK rearrangements. The PFS rate at 1 year was 42.6% for nivolumab/ipilimumab versus 13.2% for chemotherapy alone. The median PFS for nivolumab/ipilimumab was 7.2 months (95% CI, 5.5–13.2) compared with 5.5 months for chemotherapy alone (95% CI, 4.4–5.8) (HR for disease progression or death, 0.58; 95% CI, 0.41–0.81; \( P < .001 \)). The objective response rate for nivolumab/ipilimumab was 45.3% versus 26.9% with chemotherapy alone; nivolumab/ipilimumab was beneficial regardless of PD-L1 expression levels or histology. The rate of grade 3 or 4 adverse events was similar for nivolumab/ipilimumab versus chemotherapy alone (31% vs. 36%). The median PFS was not significantly different when comparing nivolumab monotherapy (N = 71) (4.2 months [95% CI, 2.7–8.3]) versus chemotherapy (N = 79) (5.6 months [95% CI, 4.5–7.0]). An earlier exploratory study assessed nivolumab monotherapy (N = 47) versus chemotherapy (N = 60) in patients with metastatic nonsquamous or squamous NSCLC who had high TMB levels. The median PFS for nivolumab monotherapy was 9.7 months (95% CI, 5.1–not reached) versus 5.8 months (95% CI, 4.2–8.5) for chemotherapy. For the 2019 update (Version 1), the NCCN NSCLC Panel now recommends (category 2A) nivolumab with or without ipilimumab for patients with high TMB levels based on these trials.

**Pembrolizumab**

**First-Line Therapy**

As previously mentioned, human immune-checkpoint–inhibitor antibodies inhibit the PD-1 receptor or PD-L1, which improves antitumor immunity; PD-1 receptors are expressed on activated cytotoxic T cells. Pembrolizumab inhibits the PD-1 receptor. The FDA approved single-agent pembrolizumab for first-line therapy based on this trial. At 6 months, the rate of overall survival was 80.2% in the pembrolizumab group versus 72.4% in the chemotherapy group (HR for death, 0.60; 95% CI, 0.41–0.89; \( P = .005 \)). Reponses were higher for pembrolizumab than for chemotherapy (44.8% vs. 27.8%). There were fewer severe treatment-related adverse events (grades 3–5) in patients receiving pembrolizumab compared with those receiving chemotherapy (26.6% vs. 53.3%). Another phase 3 randomized trial (KEYNOTE-042) compared single-agent pembrolizumab versus platinum-based chemotherapy as first-line therapy for patients with advanced nonsquamous or squamous NSCLC and PD-L1 expression levels of 50% or more, but without EGFR mutations or ALK rearrangements. The overall survival appeared to be similar in patients with PD-L1 levels of 1% to 49% who received single-agent pembrolizumab (13.4 months; 95% CI, 10.7–18.2) compared with chemotherapy (12.1 months; 95% CI, 11.0–14.0) in a subgroup analysis. However, overall survival was improved in patients with PD-L1 levels of 50% or more who received single-agent pembrolizumab (20.0 months; 95% CI, 15.4–24.9).
compared with chemotherapy (12.2 months (10.4–14.2) (HR, 0.69; 95% CI, 0.56–0.85; \( P=0.003 \)).

The NCCN NSCLC Panel recommends single-agent pembrolizumab (category 1) as the preferred first-line therapy for patients with advanced nonsquamous or squamous NSCLC, PD-L1 expression levels of 50% or more, no contraindications to immunotherapy, and negative or unknown tests results for EGFR mutations and ALK rearrangements based on the phase 3 randomized trial (KEYNOTE-024). For the 2019 update (Version 1), the panel voted that single-agent pembrolizumab is the preferred first-line therapy when compared with the pembrolizumab (or atezolizumab/bevacizumab) plus chemotherapy regimens in this setting.104 For patients who progress on first-line therapy with single-agent pembrolizumab, subsequent therapy with initial cytotoxic systemic therapy regimens (eg, carboplatin/paclitaxel) is recommended by the NCCN NSCLC Panel for the 2019 update (Version 1). For the 2019 update (Version 4), the NCCN NSCLC Panel added a new recommendation (category 2B) for single-agent pembrolizumab as first-line therapy for patients with metastatic NSCLC, PD-L1 expression levels of 1% to 49%, no contraindications to immunotherapy, and negative or unknown tests results for EGFR mutations and ALK rearrangements based on the phase 3 randomized trial (KEYNOTE-042) and FDA approval.282 The NCCN NSCLC Panel feels that single-agent pembrolizumab is useful in patients with PD-L1 levels of 1% to 49% who cannot tolerate or refuse platinum-based chemotherapy. Based on clinical trial data, the NCCN NSCLC Panel retained the category 1 preferred recommendation for single-agent pembrolizumab as first-line therapy in patients with metastatic NSCLC, PD-L1 levels of 50% or more, and negative or unknown tests results for EGFR mutations and ALK rearrangements.104,282

The NCCN NSCLC Panel recommends (category 1) IHC testing for PD-L1 expression before first-line treatment in patients with metastatic NSCLC based on the efficacy of pembrolizumab with or without chemotherapy.281 The FDA has approved a companion diagnostic biomarker test for assessing PD-L1 expression and determining which patients are eligible for pembrolizumab therapy. Although it is not an optimal biomarker, PD-L1 expression is currently the best available biomarker to assess whether patients are candidates for pembrolizumab.280,281 PD-L1 expression is continuously variable and dynamic; thus, a cutoff value for a positive result is artificial. Patients with PD-L1 expression levels just below and just above 50% will probably have similar responses.290 Unique anti-PD-L1 IHC assays are being developed for each one of the different immune checkpoint inhibitors currently in clinical trials.290,294 The definition of a positive PD-L1 test result varies depending on which biomarker assay is used.294

Ideally, PD-L1 expression levels are assessed before first-line therapy in patients with metastatic NSCLC. Every effort needs to be made to establish the genetic alteration status. If the risk of biopsy is high and genetic alteration testing is not feasible and therefore technically unknown, then it is appropriate to test for PD-L1 expression levels. Of note, plasma-based testing can be used to evaluate for EGFR mutations and ALK rearrangements, although these assays are less sensitive than tissue assays.

The NCCN NSCLC Panel recommends pembrolizumab/carboplatin (or cisplatin)/pemetrexed (category 1 preferred) as first-line therapy for patients with metastatic nonsquamous NSCLC (ie, adenocarcinoma, large cell carcinoma) or NSCLC NOS based on phase 3 and phase 2 trials (KEYNOTE-189, KEYNOTE-021) and on FDA approval (pembrolizumab/carboplatin/pemetrexed), depending on their PD-L1 expression levels.283,772 The NCCN NSCLC Panel clarified the
recommendations for pembrolizumab/chemotherapy in patients with metastatic nonsquamous NSCLC and PD-L1 expression levels of 1% to 49% for the 2019 update (Version 5); all of the regimens are a preferred category 1 recommendation in this setting. Thus, these pembrolizumab/chemotherapy regimens are recommended (category 1) as first-line therapy options for patients with no contraindications to immunotherapy, with negative or unknown test results for EGFR mutations and ALK rearrangements, regardless of their PD-L1 expression levels; however, they are preferred for those with PD-L1 levels of 50% or less. Maintenance therapy with pembrolizumab/pemetrexed is also a recommended option (category 1).

For patients who progress on combination therapy with PD-1/PD-L1 inhibitors/chemotherapy, subsequent therapy with docetaxel (with or without ramucirumab), pemetrexed (nonsquamous only), or gemcitabine is recommended if not previously given by the NCCN NSCLC Panel for the 2019 update (Version 1).

The NCCN NSCLC Panel recommends pembrolizumab/cisplatin/pemetrexed (category 1) based on a recent phase 3 randomized trial. Most patients received pembrolizumab/carboplatin/pemetrexed (72% [445/616]) in the phase 3 trial, but some received pembrolizumab/cisplatin/pemetrexed (28% [171/616]); patients did not have EGFR mutations or ALK rearrangements. The estimated rate of overall survival at 1 year was 69.2% (95% CI, 64.1%–73.8%) in patients receiving pembrolizumab-chemotherapy versus 49.4% (95% CI, 42.1%–56.2%) for chemotherapy alone (HR for death, 0.49; 95% CI, 0.38–0.64; \( P < .001 \)). After a median follow-up of 10.5 months. Overall survival was improved regardless of PD-L1 expression levels. For the pembrolizumab-chemotherapy group, median PFS was 8.8 months (95% CI, 7.6–9.2) compared with 4.9 months (95% CI, 4.7–5.5) for chemotherapy alone (HR for disease progression or death, 0.52; 95% CI, 0.43–0.64; \( P < .001 \)). Grade 3 or higher adverse events occurred at a similar rate in both arms (pembrolizumab/chemotherapy, 67.2% vs. chemotherapy, 65.8%). In a phase 2 trial (123 patients), the objective response rate was improved in patients receiving pembrolizumab/carboplatin/pemetrexed (55% [95% CI, 42%–68%]) when compared with those receiving chemotherapy alone (29% [95% CI, 18%–41%]; \( P = .0016 \)). Positive PD-L1 expression levels were not required for treatment; however, patients with PD-L1 expression of 50% or more who received pembrolizumab/carboplatin/pemetrexed had higher response rates (80% [16/20]) when compared with chemotherapy alone (35% [6/17]). There were no complete responses. The median PFS was 13 months (95% CI, 8.3–not reached) for those receiving pembrolizumab/carboplatin/pemetrexed versus 8.9 months (95% CI, 4.4–10.3) for those receiving chemotherapy alone. Overall survival rates were similar in both groups after 10.6 months of follow-up.

Treatment-related adverse events of grade 3 or worse were 39% (23/59) in the pembrolizumab/carboplatin/pemetrexed group versus 26% (16/62) in the chemotherapy alone group. Often patients received pembrolizumab maintenance therapy for 24 months. Patients also received pemetrexed maintenance therapy (85% [50/59] vs. 69% [43/62], respectively).

The NCCN NSCLC Panel recommends carboplatin/paclitaxel (or albumin-bound paclitaxel)/pembrolizumab (category 1 preferred) as first-line therapy for patients with metastatic squamous cell carcinoma NSCLC based on data from a phase 3 trial (KEYNOTE-407); 32% of patients received albumin-bound paclitaxel (also known as nab-paclitaxel). The NCCN NSCLC Panel clarified the recommendations for carboplatin/paclitaxel (or albumin-bound paclitaxel)/pembrolizumab in patients with metastatic squamous cell carcinoma NSCLC and PD-L1 expression levels of 1% to 49% for the 2019 update (Version 5); all of the regimens are a preferred category 1
recommendation in this setting. Thus, carboplatin/paclitaxel (or albumin-bound paclitaxel)/pembrolizumab is recommended (category 1) for patients with negative or unknown tests results for EGFR mutations and ALK rearrangements, regardless of PD-L1 expression levels; however, they are preferred for those with PD-L1 levels of 50% or less. Pembrolizumab/cisplatin/paclitaxel (or albumin-bound paclitaxel) is a category 2A recommended option for patients with squamous cell carcinoma NSCLC whose PD-L1 levels are less than 50%. Maintenance therapy with pembrolizumab is also a recommended option (category 2A). Patients receiving pembrolizumab/chemotherapy had an overall response rate of 58.4% compared to 35.0% for those receiving chemotherapy alone (P = .0004). Only 35% of patients had a PD-L1 tumor proportion score (TPS) less than 1%.

Subsequent Therapy

If patients have not previously received a PD-1/PD-L1 inhibitor, the NCCN NSCLC Panel recommends single-agent pembrolizumab (category 1 preferred) as subsequent therapy for patients with metastatic nonsquamous or squamous NSCLC and PD-L1 expression levels of 1% or more based on a randomized phase 2/3 trial (KEYNOTE-010), and FDA approval. Testing for PD-L1 expression levels is required before prescribing pembrolizumab. The FDA has approved pembrolizumab as subsequent therapy for patients with metastatic NSCLC whose disease has progressed after platinum-based chemotherapy if their tumors express PD-L1. Other immunotherapeutic agents are being investigated.

A randomized phase 2/3 trial (KEYNOTE-010) assessed pembrolizumab in patients with previously treated advanced nonsquamous and squamous NSCLC who were PD-L1 positive (≥1%); most patients were current or former smokers. There were 3 arms in this trial: pembrolizumab at 2 mg/kg, pembrolizumab at 10 mg/kg, and docetaxel at 75 mg/m² every 3 weeks. The median overall survival was 10.4 months for the lower dose of pembrolizumab, 12.7 months for the higher dose, and 8.5 months for docetaxel. Overall survival was significantly longer for both doses of pembrolizumab versus docetaxel (pembrolizumab 2 mg/kg: HR, 0.71; 95% CI, 0.58–0.88; P = .0008) (pembrolizumab 10 mg/kg: HR, 0.61; CI, 0.49–0.75; P < .0001). When compared with docetaxel, there were fewer grade 3 to 5 treatment-related adverse events at either dose of pembrolizumab (pembrolizumab 2 mg/kg: 13% [43/339] of patients, pembrolizumab 10 mg/kg: 16% [55/343] of patients; and docetaxel: 35% [109/309] of patients). A total of 6 treatment-related deaths occurred in patients receiving pembrolizumab (3 at each dose) and 5 treatment-related deaths occurred in the docetaxel arm.

Similar to nivolumab and atezolizumab, immune-mediated adverse events may also occur with pembrolizumab. For patients with immune-mediated adverse events, intravenous high-dose corticosteroids should be administered based on the severity of the reaction. Pembrolizumab should also be discontinued for patients with severe or life-threatening pneumonitis and should be withheld or discontinued for other severe or life-threatening immune-mediated adverse events when indicated (see prescribing information).

Atezolizumab

First-Line Therapy

The NCCN NSCLC Panel recommends atezolizumab/bevacizumab plus chemotherapy (carboplatin/paclitaxel) as first-line therapy (category 1) for patients with metastatic nonsquamous NSCLC (including
adenocarcinoma) based on a recent phase 3 randomized trial (IMpower150). This atezolizumab/bevacizumab/chemotherapy regimen is recommended as first-line therapy for patients with negative or unknown tests results for EGFR mutations and ALK rearrangements, regardless of PD-L1 expression levels. Maintenance therapy with atezolizumab, bevacizumab, or both is also a recommended option (category 1) (see Maintenance Therapy in this Discussion). Median overall survival was 19.2 months (95% CI, 17.0–23.8) in the atezolizumab arm compared with 14.7 months (95% CI, 13.3–16.9) for the control arm of carboplatin/paclitaxel/bevacizumab; the HR for death was 0.78 (95% CI, 0.64–0.96; \( P = .02 \)). PFS was increased in the atezolizumab arm versus chemotherapy/bevacizumab (8.3 vs. 6.8 months; HR, 0.62 [95% CI, 0.52–0.74]; \( P < .001 \)). Some patients with EGFR mutations or ALK rearrangements (n = 108) who had progressed on (or were intolerant of) prior TKI were enrolled in this trial, although most patients (87%) did not have these genetic alterations. In these patients with EGFR mutations or ALK rearrangements, PFS was also increased compared with chemotherapy alone (9.7 vs. 6.1 months; HR, 0.59 [95% CI, 0.37–0.94]). Therefore, this atezolizumab/bevacizumab plus chemotherapy regimen is an option for patients with EGFR mutations or ALK rearrangements who have progressed after initial therapy with TKIs.

Subsequent Therapy
If patients have not previously received a PD-1/PD-L1 inhibitor, the NCCN NSCLC Panel recommends atezolizumab (category 1 preferred) as subsequent therapy for patients with metastatic nonsquamous or squamous cell NSCLC based on a recent phase 3 trial and FDA approval. Testing for PD-L1 expression levels is not required for prescribing atezolizumab but may provide useful information. Human immune-checkpoint–inhibitor antibodies inhibit the PD-1 receptor or PD-L1, which improves antitumor immunity; PD-1 receptors are expressed on activated cytotoxic T cells. Atezolizumab inhibits PD-L1.

A phase 3 randomized trial (OAK) assessed atezolizumab versus docetaxel alone in patients with metastatic NSCLC who had progressed during or after systemic therapy. Most patients were current or former smokers and had received platinum-based chemotherapy; few patients (10%) had EGFR mutations and ALK rearrangements were not reported. Data show that patients with nonsquamous NSCLC who received atezolizumab had improved overall survival when compared with those receiving docetaxel (15.6 vs. 11.2 months; HR, 0.73 [0.6–0.89]; \( P = .0015 \)). Overall survival was only slightly improved in patients with squamous cell NSCLC receiving atezolizumab versus docetaxel (8.9 vs. 7.7 months; HR, 0.73 [0.54–0.98]; \( P = .038 \)); there were fewer patients in the squamous group when compared with the nonsquamous group (222 vs. 628). There were fewer treatment-related severe adverse events (grades 3–4) for atezolizumab versus docetaxel (15% vs. 43% [90/609 vs. 247/578]).

Similar to nivolumab and pembrolizumab, immune-mediated adverse events may also occur with atezolizumab. For patients with immune-mediated adverse events, intravenous high-dose corticosteroids should be administered based on the severity of the reaction. Atezolizumab should also be permanently discontinued for patients with severe or life-threatening pneumonitis and should be discontinued for other severe or life-threatening immune-mediated adverse events when indicated (see prescribing information).

Maintenance Therapy
Maintenance therapy refers to systemic therapy that may be given for patients with advanced NSCLC after 4 to 6 cycles of first-line chemotherapy. Patients are only candidates for maintenance therapy if their tumors have responded to their previous treatment (ie, tumor response) or have stable disease and their tumors have not progressed. Continuation maintenance therapy refers to the use of at least one of the
agents that was given in the first-line regimen. *Switch maintenance* therapy refers to the initiation of a different agent that was not included as part of the first-line regimen. Selection of appropriate maintenance therapy depends on several factors (eg, histologic type, presence of mutations or gene rearrangements, PS). Maintenance therapy is an option in the NCCN Guidelines for select patients with tumor response or stable disease and is not recommended for all patients (eg, not recommended for PS 3–4, those with progression); close observation (category 2A) is also a valid treatment option (see the NCCN Guidelines for NSCLC).\(^{781}\)

**Continuation Maintenance Therapy**

For continuation maintenance therapy, select agents (which were initially given in combination with conventional chemotherapy) may be continued until evidence of disease progression or unacceptable toxicity based on the design of the clinical trials that led to their approval. Single-agent bevacizumab (category 1) may be continued beyond 4 to 6 cycles of initial therapy (ie, platinum-doublet chemotherapy given with bevacizumab or atezolizumab/carboplatin/paclitaxel/bevacizumab) in patients with nonsquamous NSCLC.\(^{251,782,783}\) Single-agent pemetrexed (category 1) may also be given as continuation maintenance therapy in patients with nonsquamous NSCLC if given in the initial regimen.\(^{782,784}\) A phase 3 randomized trial (PARAMOUNT) found that continuation maintenance therapy with pemetrexed slightly increased PFS when compared with placebo (4.1 vs. 2.8 months).\(^{784}\) Results show that continuation maintenance therapy with pemetrexed also improves overall survival (13.9 vs. 11.0 months).\(^{785}\) Based on the trial and the FDA approval, the NCCN NSCLC Panel recommends single-agent pemetrexed as continuation maintenance therapy (category 1) in patients with nonsquamous NSCLC.

Continuation maintenance therapy using bevacizumab/pemetrexed (category 2A) is also an option in patients with nonsquamous NSCLC if initially given as part of a bevacizumab/pemetrexed/platinum regimen.

Data from the POINTBREAK study reported a very slight improvement in PFS (6 vs. 5.6 months) when comparing bevacizumab/pemetrexed versus bevacizumab alone as maintenance therapy; the initial regimens were either bevacizumab/carboplatin/pemetrexed or bevacizumab/carboplatin/paclitaxel.\(^{654}\) It is important to note that the pemetrexed-based arm was associated with less toxicity (eg, less neurotoxicity, less neutropenia, less hair loss) than the paclitaxel-based arm. When using bevacizumab/pemetrexed versus bevacizumab alone as maintenance therapy, data from the AVAPERL study showed a 3.7-month increase in PFS (7.4 vs. 3.7 months); the initial regimen was bevacizumab/cisplatin/pemetrexed.\(^{786,787}\)

Continuation maintenance therapy with atezolizumab, bevacizumab, or both is also a recommended option (category 1) in patients with metastatic nonsquamous NSCLC who have received atezolizumab/carboplatin/paclitaxel/bevacizumab.\(^{284}\) In the clinical trial, patients received maintenance therapy until disease progression or development of toxic side effects that were not manageable. In patients who received maintenance therapy with atezolizumab, bevacizumab, or both, there was a low rate of serious adverse reactions. Likewise, if patients with metastatic nonsquamous NSCLC have received pembrolizumab/carboplatin (or cisplatin)/pemetrexed, then continuation maintenance therapy with pembrolizumab/pemetrexed is also a recommended option (category 1).\(^{283}\) Patients received maintenance therapy until disease progression or development of toxic side effects that were not manageable.

A phase 3 randomized trial compared using maintenance therapy with either gemcitabine or erlotinib after first-line therapy with cisplatin-gemcitabine. Continuation maintenance therapy with single-agent gemcitabine was reported to increase PFS to a greater extent (3.8 months) than switch maintenance therapy with erlotinib (2.9 months) when
compared with observation (1.9 months).\textsuperscript{788,789} Another phase 3 randomized trial assessed continuation maintenance therapy with gemcitabine versus best supportive care after an initial regimen of cisplatin/gemcitabine.\textsuperscript{790} The data showed a slight difference in PFS but no difference in overall survival. The NCCN Guidelines recommend using gemcitabine (category 2B) as continuation maintenance therapy regardless of histology in patients without ALK rearrangements, sensitizing EGFR mutations, or PD-L1 expression. Use of continuation maintenance therapy depends on several factors, such as whether the patient had minimal toxicity during treatment. A drug vacation may be more appropriate for some patients.\textsuperscript{652} Some clinicians feel that continuation maintenance therapy is only appropriate for select patients, because it has only been shown to improve overall survival or quality of life for a few agents and not all agents, although it has been shown to improve PFS.\textsuperscript{652,791} In addition, maintenance therapy has not been shown to be superior to subsequent therapy, which is initiated at disease progression. A phase 3 randomized trial suggests that conventional cytotoxic agents should not be continued beyond 4 to 6 cycles of therapy; however, many patients assigned to a longer duration of therapy did not receive the planned number of cycles (see Maintenance Therapy in this Discussion).\textsuperscript{791,792}

**Switch Maintenance Therapy**

Issues have been raised about switch maintenance therapy, including the design of the trials, modest survival benefits, quality of life, and toxicity.\textsuperscript{652,793} Two phase 3 randomized trials reported a benefit in PFS and overall survival with the initiation of pemetrexed after first-line chemotherapy (4–6 cycles) in patients with nonsquamous NSCLC and no apparent disease progression.\textsuperscript{794,795} Switch maintenance therapy with pemetrexed is recommended in patients with nonsquamous cell carcinoma; negative or unknown test results for ALK rearrangements or sensitizing EGFR mutations; and PD-L1 expression less than 1% or unknown.\textsuperscript{795} The FDA has approved maintenance therapy with pemetrexed.\textsuperscript{796}

Recently, the NCCN NSCLC Panel revised the recommendation for switch maintenance therapy with pemetrexed to category 2A (from 2B) based on clinical experience and reassessment of trial data (see Maintenance Therapy in this Discussion).\textsuperscript{795} The NCCN NSCLC Panel does not recommend erlotinib as switch maintenance therapy (or as subsequent therapy) for patients with nonsquamous NSCLC and good PS but without EGFR mutations based on results from a randomized trial (IUNO) and revised indication from the FDA.\textsuperscript{797} The NCCN NSCLC Panel also deleted the recommendations for switch maintenance therapy with erlotinib in patients with squamous cell NSCLC, because overall survival and quality of life were not improved.\textsuperscript{788,798} A phase 3 trial assessed switch maintenance therapy with docetaxel given either immediately after chemotherapy or delayed until progression.\textsuperscript{799} Switch maintenance therapy with docetaxel is a category 2B recommendation in the NCCN Guidelines for patients with squamous cell carcinoma, because many patients in the delayed chemotherapy arm did not receive docetaxel.

**Clinical Evaluation**

The workup and evaluation of incidental lung nodules that are detected on imaging for other conditions is described in the NSCLC algorithm (see Incidental Lung Nodules in this Discussion and the NCCN Guidelines for NSCLC). Recently, the NCCN NSCLC Panel revised the diagnostic algorithms for incidental solid and subsolid lung nodules detected on chest CT based on the updated Fleischner criteria (see the NCCN Guidelines for NSCLC).\textsuperscript{70-74} The cutoff thresholds have been increased to 6 mm for a positive scan result. As previously described, low-dose CT screening is recommended for asymptomatic select patients who are at high risk for lung cancer and management of these nodules is described elsewhere.
After patients are confirmed to have NSCLC based on a pathologic diagnosis, a clinical evaluation needs to be done (see the NCCN Guidelines for NSCLC). In patients with symptoms, the clinical stage is initially determined from disease history (ie, cough, dyspnea, chest pain, weight loss) and physical examination together with a limited battery of tests (see Evaluation and Clinical Stage in the NCCN Guidelines for NSCLC). The NCCN NSCLC Panel also recommends that smoking cessation advice, counseling, and pharmacotherapy be provided to patients. After the clinical stage is determined, the patient is assigned to one of the pathways that are defined by the stage, specific subdivision of the particular stage, and location of the tumor. Note that for some patients, diagnosis, staging, and surgical resection are done during the same operative procedure. A multidisciplinary evaluation should be done before treatment.

### Additional Pretreatment Evaluation

As previously noted, evaluation of the mediastinal nodes is a key step in the further staging of the patient. FDG PET/CT scans can be used as an initial assessment of the hilar and mediastinal nodes (ie, to determine whether the N1, N2, or N3 nodes are positive for cancer, which is a key determinant of stage II and stage III disease); however, CT scans have known limitations for evaluating the extent of lymph node involvement in lung cancer. When compared with noninvasive staging methods (EBUS, EUS), surgical staging with mediastinoscopy is more appropriate for certain settings when evaluating mediastinal nodes; however, clinicians use both methods when staging patients. Thus, mediastinoscopy is encouraged as part of the initial evaluation, particularly if the results of imaging are not conclusive and the probability of mediastinal involvement is high (based on tumor size and location).

Therefore, mediastinoscopy is appropriate for patients with T2 to T3 lesions even if the FDG PET/CT scan does not suggest mediastinal node involvement.

Mediastinoscopy may also be appropriate to confirm mediastinal node involvement in patients with a positive FDG PET/CT scan. In patients with solid tumors less than 1 cm or those with purely nonsolid tumors (ie, GGOs) less than 3 cm, pathologic mediastinal lymph node evaluation is optional if the nodes are FDG PET/CT negative because there is a low likelihood of positive mediastinal nodes. Mediastinoscopy can be considered in patients with clinical stage 1A disease (T1ab,N0). In patients with peripheral T2a, central T1ab, or T2a lesions with negative FDG PET/CT scans, the risk for mediastinal lymph node involvement is higher and mediastinoscopy and/or EUS-FNA and EBUS-TBNA are recommended. Dillemans et al have reported a selective mediastinoscopy strategy, proceeding straight to thoracotomy without mediastinoscopy for T1 peripheral tumors without enlarged mediastinal lymph nodes on preoperative CT. This strategy resulted in a 16% incidence of positive N2 nodes discovered only at the time of thoracotomy.

For identifying N2 disease, chest CT scans had sensitivity and specificity rates of 69% and 71%, respectively. Using the chest CT scan plus mediastinoscopy was significantly more accurate (89% vs. 71%) than using the chest CT scan alone for identifying N2 disease. When using CT scans, node positivity is based on the size of the lymph nodes. Therefore, the CT scan will miss small metastases that do not result in node enlargement. To address this issue, Arita et al specifically examined lung cancer metastases to normal size mediastinal lymph nodes in 90 patients and found an incidence of 16% (14/90) false-negative chest CT scans with histologic identification of occult N2 or N3 disease. Bronchoscopy is used in diagnosis and local staging of both central and peripheral lung lesions and is recommended for pretreatment evaluation of stage I to IIIA.

(see the NCCN Guidelines for Lung Cancer Screening, available at www.NCCN.org).

tumors. In patients who present with a solitary pulmonary nodule where the suspicion of malignancy is high, surgical resection without prior invasive testing may be reasonable.

As previously mentioned, CT scans have known limitations for evaluating the extent of lymph node involvement in lung cancer. PET scans have been used to help evaluate the extent of disease and to provide more accurate staging. The NCCN NSCLC Panel reviewed the diagnostic performance of CT and PET scans. The NCCN NSCLC Panel believes that PET scans can play a role in the evaluation and more accurate staging of NSCLC, for example, in identifying stage I (peripheral and central T1–2,N0), stage II, stage III, and stage IV diseases. However, FDG PET/CT is even more sensitive and is recommended by NCCN. PET/CT is typically done from the skull base to the knees; whole body PET/CT may also be done.

The NCCN NSCLC Panel assessed studies that examined the sensitivity and specificity of chest CT scans for mediastinal lymph node staging. Depending on the clinical scenario, a sensitivity of 40% to 65% and a specificity of 45% to 90% were reported. Because they detect tumor physiology, as opposed to anatomy, PET scans may be more sensitive than CT scans. Moreover, if postobstructive pneumonitis is present, there is little correlation between the size of the mediastinal lymph nodes and tumor involvement. Chin et al found that PET, when used to stage the mediastinal nodes, was 78% sensitive and 81% specific with a negative predictive value of 89%. Kernstine et al compared PET scan to CT scan for identifying N2 and N3 disease in NSCLC. The PET scan was found to be more sensitive than the CT scan in identifying mediastinal node disease (70% vs. 65%). FDG PET/CT has been shown to be useful in restaging patients after adjuvant therapy.

When patients with early-stage disease are accurately staged using FDG PET/CT, inappropriate surgery is avoided. Positive FDG PET/CT scan findings for distant disease need pathologic or other radiologic confirmation (eg, MRI of bone). If the FDG PET/CT scan is positive in the mediastinum, the lymph node status needs pathologic confirmation. Transesophageal EUS-FNA and EBUS-TBNA have proven useful to stage patients or to diagnose mediastinal lesions; these techniques can be used instead of invasive staging procedures in select patients. When compared with CT and PET, EBUS-TBNA has a high sensitivity and specificity for staging mediastinal and hilar lymph nodes in patients with lung cancer. In patients with positive nodes on CT or PET, EBUS-TBNA can be used to clarify the results. In patients with negative findings on EBUS-TBNA, conventional mediastinoscopy can be done to confirm the results. Note that EBUS is also known as endosonography.

The routine use of bone scans (to exclude bone metastases) is not recommended. Brain MRI (with contrast) is recommended to rule out asymptomatic brain metastases in patients with stage II, III, and IV disease if aggressive combined-modality therapy is being considered. Patients with stage IB NSCLC are less likely to have brain metastases; therefore, brain MRI is optional in this setting and can be considered for select patients at high risk (eg, tumors greater than 5 cm, central location). If brain MRI cannot be done, then CT of the head with contrast is an option. Note that PET scans are not recommended for assessing whether brain metastases are present (see the NCCN Guidelines for Central Nervous System Cancers, available at www.NCCN.org).

**Initial Therapy**

As previously mentioned, accurate pathologic assessment and staging are essential before treatment for NSCLC, because management varies depending on the stage, histology, presence of genetic alterations, and PS. Before treatment, it is strongly recommended that determination of tumor resectability be made by board-certified thoracic surgeons who perform lung cancer surgery as a prominent part of their practice (see
Principles of Surgical Therapy in the NCCN Guidelines for NSCLC).
Principles of Radiation Therapy recommends doses for RT (see the NCCN Guidelines for NSCLC). In addition, the NCCN Guidelines also recommend regimens for chemotherapy and chemoradiation (see Chemotherapy Regimens for Neoadjuvant and Adjuvant Therapy, Chemotherapy Regimens Used with Radiation Therapy, and Systemic Therapy for Advanced or Metastatic Disease in the NCCN Guidelines for NSCLC). Targeted therapy is recommended for patients with metastatic NSCLC and positive test results for ALK or ROS1 rearrangements, BRAF V600E mutations, or sensitizing EGFR mutations.

Stage I, Stage II, and Stage IIIA Disease
Depending on the extent and type of comorbidity present, patients with stage I or a subset of stage II (T1–2,N1) tumors are generally candidates for surgical resection and mediastinal lymph node dissection. Definitive RT, including SABR, is recommended for patients with early-stage NSCLC who are medically inoperable or refuse surgery; RT can be considered as an alternative to surgery in patients at high risk of complications (see Stereotactic Ablative Radiotherapy in this Discussion and see Initial Treatment for Stage I and II in the NCCN Guidelines for NSCLC). In some instances, positive mediastinal nodes (N2) are discovered at surgery; in this setting, an additional assessment of staging and tumor resectability must be made, and the treatment (ie, inclusion of systematic mediastinal lymph node dissection) must be modified accordingly. Therefore, the NCCN Guidelines include 2 different tracks for T1–2,N2 disease (ie, stage IIIA disease): 1) T1–2,N2 disease discovered unexpectedly at surgical exploration; and 2) T1–2,N2 disease confirmed before thoracotomy. In the second case, an initial brain MRI (with contrast) and FDG PET/CT scan (if not previously done) are recommended to rule out metastatic disease.

For patients with clinical stage IIB (T3,N0) and stage IIIA tumors who have different treatment options (surgery, RT, or chemotherapy), a multidisciplinary evaluation is recommended. For the subsets of stage IIB (T3,N0) and stage IIIA (T4,N0–1) tumors, treatment options are organized according to the location of the tumor such as the superior sulcus, chest wall, proximal airway, or mediastinum.304 For each location, a thoracic surgeon needs to determine whether the tumor is resectable (see Principles of Surgical Therapy in the NCCN Guidelines for NSCLC).

For patients with resectable tumors (T3 invasion,N0–1) in the superior sulcus, the NCCN NSCLC Panel recommends preoperative concurrent chemoradiation therapy followed by surgical resection and chemotherapy (see Initial Treatment for Superior Sulcus Tumors in the NCCN Guidelines for NSCLC). Preoperative concurrent chemoradiation followed by surgical resection of a superior sulcus tumor has shown 2-year survival in the 50% to 70% range.304,404,406,833-836 The overall 5-year survival rate is approximately 40%.404,837 Patients with possibly resectable superior sulcus tumors should undergo preoperative concurrent chemoradiation before surgical re-evaluation (including CT ± PET/CT). For patients with unresectable tumors (T4 extension,N0–1) in the superior sulcus, definitive concurrent chemoradiation is recommended. Two additional cycles of full-dose chemotherapy can be given if full-dose chemotherapy was not given concurrently with RT.637,838 The NCCN NSCLC Panel recommends durvalumab (category 1) as consolidation immunotherapy after treatment with definitive concurrent chemoradiation for patients with unresectable stage III NSCLC based on data from a phase 3 randomized trial (see Chemoradiation: Trial Data in this Discussion and the NCCN Guidelines for NSCLC).279 The recommendation for consolidation immunotherapy with durvalumab occurs in multiple places in the NCCN Guidelines.

Surgical resection is the preferred treatment option for patients with tumors of the chest wall, proximal airway, or mediastinum (T3–4,N0–1).
Other treatment options include preoperative chemotherapy or concurrent chemoradiation before surgical resection. For unresectable tumors (T4,N0–1) without pleural effusion, definitive concurrent chemoradiation (category 1) is recommended followed by consolidation immunotherapy with durvalumab (category 1). For the 2019 update (Version 1), the panel deleted the recommendation to add an additional 2 cycles of full-dose chemotherapy if patients have not received full-dose chemotherapy concurrently with RT, based on concerns that consolidation chemotherapy will increase the risk of pneumonitis if patients are also receiving durvalumab. However, consolidation chemotherapy is an option if patients are not receiving durvalumab.

Multimodality therapy is recommended for most patients with stage III NSCLC. For patients with stage IIIA disease and positive mediastinal nodes (T1–2,N2), treatment is based on the findings of pathologic mediastinal lymph node evaluation (see the NCCN Guidelines for NSCLC). Patients with negative mediastinal biopsy findings are candidates for surgery. For those patients with resectable lesions, mediastinal lymph node dissection or lymph node sampling should be performed during the operation. Those individuals who are medically inoperable should be treated according to the clinical stage (see the NCCN Guidelines for NSCLC). For patients with (T1–2) N2 node-positive disease, a brain MRI (with contrast) and FDG PET/CT scan (if not done previously) are recommended to search for distant metastases. When distant metastases are not present, the NCCN NSCLC Panel recommends that the patient be treated with definitive concurrent chemoradiation therapy (see the NCCN Guidelines for NSCLC). Recommended therapy for metastatic disease depends on whether disease is in a solitary site or is widespread (see the NCCN Guidelines for NSCLC).

When a lung metastasis is present, it usually occurs in a patient with other systemic metastases; the prognosis is poor. Therefore, many of these patients are not candidates for surgery; however, systemic therapy is recommended. Although uncommon, patients with lung metastases but without systemic metastases have a better prognosis and are candidates for surgery (see Multiple Lung Cancers in this Discussion). Patients with separate pulmonary nodule(s) in the same lobe (T3,N0–1) or ipsilateral non-primary lobe (T4,N0–1) without other systemic metastases are potentially curable by surgery; 5-year survival rates are about 30%. For those with N2 nodes after surgery, concurrent chemoradiation is recommended for those with positive margins and an R2 resection; either sequential or concurrent chemoradiation is recommended after an R1 resection. Most NCCN Member Institutions favor concurrent chemoradiation for positive margins, but sequential chemoradiation is reasonable in frailer patients. Chemotherapy alone is recommended for those with N2 nodes and negative margins, sequential chemotherapy (category 1) with RT is recommended. Chemotherapy alone is recommended for those with N0–1 nodes (see the NCCN Guidelines for NSCLC). In patients with synchronous solitary nodules (contralateral lung), the NCCN NSCLC Panel recommends treating them as 2 primary lung tumors if both are curable, even if the histology of the 2 tumors is similar (see the NCCN Guidelines for NSCLC).

Multiple Lung Cancers

Patients with a history of lung cancer or those with biopsy-proven synchronous lesions may be suspected of having multiple lung cancers (see Clinical Presentation in the NCCN Guidelines for NSCLC). It is important to determine whether the multiple lung cancers are metastases or separate lung primaries (synchronous or metachronous), because most multiple lung tumors are metastases. Therefore, it is essential to determine the histology of the lung tumor (see Principles of Pathologic Review in the NCCN Guidelines for NSCLC). Infection and other benign diseases also need to be ruled out (eg, inflammatory granulomas). Although criteria have been established for diagnosing multiple lung
cancers, no definitive method has been established before treatment.\cite{847-850} The Martini and Melamed criteria are often used to diagnose multiple lung cancers as follows: 1) the histologies are different; or 2) the histologies are the same, but there is no lymph node involvement and no extrathoracic metastases.\cite{850}

Treatment of multiple lung cancers depends on the status of the lymph nodes (eg, N0–1) and on whether the lung cancers are asymptomatic, symptomatic, or at high or low risk of becoming symptomatic (see Initial Treatment in the NCCN Guidelines for NSCLC).\cite{844,851-853} Patients should be evaluated in a multidisciplinary setting (eg, surgeons, radiation oncologists, medical oncologists). In patients eligible for definitive local therapy, parenchymal-sparing resection is preferred (see the Principles of Surgical Therapy in the NCCN Guidelines for NSCLC).\cite{843,844} VATS or SABR are reasonable options depending on the number and distribution of the tumors requiring local treatment.\cite{854} Multiple lung nodules (eg, solid, subsolid nodules) may also be detected on CT scans; some of these nodules can be followed with imaging, whereas others need to be biopsied or excised (see Incidental Lung Nodules in this Discussion and the NCCN Guidelines for Lung Cancer Screening, available at www.NCCN.org).\cite{855}

### Stage IIIB Disease

Stage IIIB tumors comprise 2 unresectable groups, including: 1) T1–2,N3 tumors; and 2) T3–4,N2 tumors, which include contralateral mediastinal nodes (T4,N3). Surgical resection is not recommended in patients with T1–2,N3 disease. However, in patients with suspected N3 disease, the NCCN Guidelines recommend pathologic confirmation of nodal status (see Pretreatment Evaluation in the NCCN Guidelines for NSCLC).\cite{856,857} In addition, FDG PET/CT scans (if not previously done) and brain MRI (with contrast) should also be included in the pretreatment evaluation. If these imaging tests are negative, then treatment options for the appropriate nodal status should be followed (see the NCCN Guidelines for NSCLC). If N3 disease is confirmed, definitive concurrent chemoradiation (category 1) is recommended; 2 additional cycles of full-dose chemotherapy can be given if full-dose chemotherapy was not given concurrently with RT.\cite{323,590,637,858,859} As previously mentioned, durvalumab is recommended (category 1) as consolidation immunotherapy after treatment with definitive concurrent chemoradiation for patients with unresectable stage III NSCLC (see Chemoradiation: Trial Data in this Discussion and the NCCN Guidelines for NSCLC).\cite{279} For metastatic disease that is confirmed by FDG PET/CT scan and brain MRI (with contrast), treatment is described in the NCCN Guidelines for limited or metastatic disease.

For patients with T4,N2–3 disease (stage IIIB), surgical resection is not recommended. The initial workup includes biopsies of the N3 and N2 nodes. If these biopsies are negative, the same treatment options may be used as for stage IIIA (T4,N0–1) disease (see the NCCN Guidelines for NSCLC). If either the contralateral or ipsilateral mediastinal node is positive, definitive concurrent chemoradiation therapy is recommended (category 1) followed by 2 cycles of full-dose chemotherapy if full-dose chemotherapy was not given concurrently with RT as initial treatment (see the NCCN Guidelines for NSCLC).\cite{323,590,637,858-860} Again, durvalumab is recommended (category 1) after definitive concurrent chemoradiation for patients with unresectable stage III NSCLC.\cite{279}

### Stage IV Disease

In general, systemic therapy is recommended for patients with metastatic disease (see Systemic Therapy for Advanced or Metastatic Disease in the NCCN Guidelines for NSCLC).\cite{596} In addition, palliative treatment, including RT, may be needed during the disease course to treat localized symptoms, diffuse brain metastases, or bone metastases (see Therapy for Recurrence and Metastasis in the NCCN Guidelines for NSCLC). This section focuses on patients with limited metastatic disease; management of widespread distant metastases is described in another section (see...
Pleural or pericardial effusion is a criterion for stage IV, M1a disease. T4 with pleural effusion is classified as stage IV, M1a (see Table 3 in Staging in the NCCN Guidelines for NSCLC). Pleural or pericardial effusions are malignant in 90% to 95% of patients; however, they may be related to obstructive pneumonitis, atelectasis, lymphatic or venous obstruction, or a pulmonary embolus. Therefore, pathologic confirmation of a malignant effusion by using thoracentesis or pericardiocentesis is recommended. In certain cases where thoracentesis is inconclusive, thoracoscopy may be performed. In the absence of nonmalignant causes (eg, obstructive pneumonia), an exudate or sanguinous effusion is considered malignant regardless of the results of cytologic examination. If the pleural or pericardial effusion is considered negative for malignancy (M0), recommended treatment is based on the confirmed T and N stage (see the NCCN Guidelines for NSCLC). All pleural or pericardial effusions, whether malignant or not, are associated with unresectable disease in 95% of cases. In patients with effusions that are positive for malignancy, the tumor is defined as M1a and is treated with local therapy (ie, ambulatory small catheter drainage, pleurodesis, and pericardial window) in addition to treatment as for stage IV disease (see the NCCN Guidelines for NSCLC).

Management of patients with distant metastases in limited sites (ie, stage IVA, M1b) and good PS depends on the location and number of the metastases; the diagnosis is aided by mediastinoscopy, bronchoscopy, FDG PET/CT scan, and brain MRI (with contrast). The increased sensitivity of FDG PET/CT scans, compared with other imaging methods, may identify additional metastases and, thus, spare some patients from unnecessary futile surgery. Positive FDG PET/CT scan findings for distant disease need pathologic or other radiologic confirmation. If the FDG PET/CT scan is positive in the mediastinum, the lymph node status needs pathologic confirmation. Patients with limited oligometastatic disease (eg, brain metastases) and otherwise limited disease in the chest may benefit from aggressive local therapy to both the primary chest and metastatic sites. The NCCN NSCLC Panel recently revised the recommendations for treatment of limited brain metastases by decreasing recommendations for whole brain RT (see Whole Brain RT and Stereotactic Radiosurgery in this Discussion text). Clinicians are not using whole brain RT as often in patients with limited brain metastases because of concerns about neurocognitive problems. Aggressive local therapy may comprise surgery and/or definitive RT including SRS and SABR, and may be preceded or followed by chemotherapy. After progression on TKIs, patients with EGFR mutations may be able to continue with their current TKIs; local therapy can be considered to treat their limited metastases (eg, SRS to brain metastases or other sites, SABR for thoracic disease).

Postoperative Treatment
Chemotherapy or Chemoradiation
Post-surgical treatment options for patients with stage IA tumors (T1abc,N0) and with positive surgical margins (R1, R2) include re-resection (preferred) or RT (category 2B). Observation is recommended for patients with T1abc–T2ab,N0 tumors and with negative surgical margins (R0). Postoperative chemotherapy is a category 2A recommendation for patients with T2ab,N0 tumors and negative surgical margins who have high-risk features (including poorly differentiated tumors, vascular invasion, wedge resection, tumors >4 cm, visceral pleural involvement, and unknown lymph node status [Nx]) (see the NCCN Guidelines for NSCLC). If the surgical margins are positive in patients with T2ab,N0 tumors, options include: 1) re-resection (preferred) with (or without) chemotherapy; or 2) RT with (or without) chemotherapy (chemotherapy is recommended for T2b,N0).
The NCCN NSCLC Panel recommends chemotherapy (category 1) for patients with negative surgical margins and stage IIB disease, including 1) T1abc–T2a,N1; 2) T2b,N1; or 3) T3,N0 disease.\textsuperscript{617,867} If surgical margins are positive in these patients, options after an R1 resection include: 1) re-resection and chemotherapy; or 2) chemoradiation (either sequential or concurrent). Options after an R2 resection include: 1) re-resection and chemotherapy; or 2) concurrent chemoradiation. Most NCCN Member Institutions favor concurrent chemoradiation for positive margins, but sequential chemoradiation is reasonable in frailer patients.\textsuperscript{633}

Postoperative chemotherapy can also be used in patients with stage III NSCLC who have had surgery (see the NCCN Guidelines for NSCLC). Patients with T1–3,N2 or T3,N1 disease (discovered only at surgical exploration and mediastinal lymph node dissection) and positive margins may be treated with chemoradiation; either sequential or concurrent chemoradiation is recommended for an R1 resection, whereas concurrent chemoradiation is recommended for an R2 resection (see the NCCN Guidelines for NSCLC). Patients with negative margins may be treated with either 1) chemotherapy (category 1); or 2) sequential chemotherapy plus RT (for N2 only).\textsuperscript{617}

For stage IIIA superior sulcus tumors (T4 extension,N0–1) that become resectable after preoperative concurrent chemoradiation, resection followed by chemotherapy is recommended (see the NCCN Guidelines for NSCLC). Surgical reevaluation (including chest CT with or without contrast and with or without PET/CT) is done to determine whether the tumor is resectable after treatment. If the lesion remains unresectable after preoperative concurrent chemoradiation, the full course of definitive chemo/RT should be completed followed by durvalumab (category 1 for durvalumab). Among patients with chest wall lesions with T3 invasion–T4 extension,N0–1 disease, those who are initially treated with surgery (preferred) may receive chemotherapy alone if the surgical margins are negative. When surgical margins are positive, they may receive either 1) sequential or concurrent chemoradiation; or 2) re-resection and chemotherapy. As previously mentioned, most NCCN Member Institutions favor concurrent chemoradiation for positive margins, but sequential is reasonable in frailer patients.\textsuperscript{633} A similar treatment plan is recommended for resectable tumors of the proximal airway or mediastinum (T3–4,N0–1).

For patients with stage III disease and positive mediastinal nodes (T1–3,N2) with no apparent disease progression after initial treatment, recommended treatment includes surgery with (or without) RT (if not given preoperatively) and/or with (or without) chemotherapy (category 2B for chemotherapy) (see the NCCN Guidelines for NSCLC). Alternatively, if the disease progresses, patients may be treated with either 1) local therapy using RT (if not given previously) with (or without) chemotherapy; or 2) systemic therapy. In patients with separate pulmonary nodules in the same lobe (T3,N0–1) or ipsilateral non-primary lobe (T4,N0–1), surgery is recommended. In patients with N2 disease and negative margins, options include 1) chemotherapy (category 1); or 2) sequential chemotherapy with radiation. If the resection margins are positive in patients with N2 disease, concurrent chemoradiation is recommended for an R2 resection, whereas either concurrent or sequential chemoradiation is recommended for an R1 resection. Concurrent chemoradiation is often used for positive margins, but sequential is reasonable in frailer patients.

Because patients with stage III disease have both local and distant failures, theoretically, the use of chemotherapy may eradicate micrometastatic disease obviously present but undetectable at diagnosis. The timing of this chemotherapy varies (see the NCCN Guidelines for NSCLC). Such chemotherapy may be given alone, sequentially, or concurrently with RT. In addition, chemotherapy could be given preoperatively or postoperatively in appropriate patients.

On the basis of clinical studies,\textsuperscript{578-580} the NCCN NSCLC Panel recommends cisplatin combined with docetaxel, etoposide, gemcitabine,
or vinorelbine for postoperative chemotherapy for all histologies in the NCCN Guidelines; other options include cisplatin combined with pemetrexed for nonsquamous NSCLC (see *Chemotherapy Regimens for Neoadjuvant and Adjuvant Therapy* in the NCCN Guidelines for NSCLC). For patients with comorbidities or those who cannot tolerate cisplatin, carboplatin may be combined with pemetrexed (nonsquamous only), paclitaxel, or gemcitabine. Recently, the NCCN NSCLC Panel expanded the list of regimens for sequential chemoradiation to include regimens that are also used for preoperative and postoperative chemotherapy (ie, cisplatin combined with pemetrexed [nonsquamous only], docetaxel, etoposide, gemcitabine, or vinorelbine; carboplatin combined with paclitaxel) and also added 2 new carboplatin regimens for patients with comorbidities or those not able to tolerate cisplatin, including 1) carboplatin/gemcitabine; and 2) carboplatin/pemetrexed (nonsquamous only).

Three phase 3 trials have assessed preoperative chemotherapy followed by surgery compared with surgery alone in the treatment of stage III NSCLC. The S9900 trial (a SWOG study)—one of the largest randomized trials examining preoperative chemotherapy in early-stage NSCLC—assessed surgery alone compared with surgery plus preoperative paclitaxel/carboplatin in patients with stage IB/IIA and stage IIB/IIIA NSCLC (excluding superior sulcus tumors). PFS and overall survival were improved with preoperative chemotherapy. All 3 studies showed a survival advantage for patients who received preoperative chemotherapy. The 2 earlier phase 3 studies had a small number of patients, while the SWOG study was stopped early because of the positive results of the IALT study. A number of phase 2 studies have evaluated preoperative chemotherapy for stage III NSCLC, with (or without) RT, followed by surgery.

**Radiation Therapy**

After complete resection of clinical early-stage NSCLC, postoperative RT has been found to be detrimental for pathologic N0 or N1 stage disease in a meta-analysis of small randomized trials using older techniques and dosing regimens and a population-based analysis of data from SEER. There was an apparent survival benefit of postoperative RT in patients with N2 nodal stage diagnosed surgically. The analysis of the ANITA trial also found that postoperative RT increased survival in patients with N2 disease who received chemotherapy. A review of the National Cancer Database concluded that postoperative RT and chemotherapy provided a survival advantage for patients with completely resected N2 disease when compared with chemotherapy alone. A recent meta-analysis also concluded that postoperative RT improves survival for patients with N2 disease. Postoperative sequential chemotherapy with RT is recommended for patients with T1–3, N2 disease and negative margins (see the NCCN Guidelines for NSCLC). A meta-analysis assessed postoperative chemotherapy with (or without) postoperative RT in patients mainly with stage III disease. In this meta-analysis, 70% of the eligible trials used sequential chemotherapy before RT; 30% used concurrent chemo/RT. Regimens included cisplatin/vinorelbine followed by RT or concurrent cisplatin/etoposide.

The ACR Appropriateness Criteria® provide specific recommendations for postoperative therapy. Either concurrent or sequential chemoradiation may be used for postoperative therapy, depending on the type of resection and the setting (eg, N2 disease) (see the NCCN Guidelines for NSCLC). Concurrent chemo/RT is recommended for R2 resections, whereas either sequential or concurrent chemo/RT is recommended for R1 resections. Concurrent chemoradiation is often used for positive margins, but sequential is reasonable in frailer patients. Cisplatin/etoposide, cisplatin/vinblastine, and carboplatin/paclitaxel are chemoradiation regimens recommended by the NCCN NSCLC Panel for
all histologies (see Chemotherapy Regimens Used with Radiation Therapy in the NCCN Guidelines for NSCLC). Pemetrexed with either cisplatin or carboplatin may be used for concurrent chemoradiation in patients with nonsquamous NSCLC. When chemoradiation is recommended in the NCCN Guidelines, these regimens may be used for stage II to III disease.

A phase 3 trial (PROCLAIM) assessed concurrent thoracic RT with cisplatin/pemetrexed versus cisplatin/etoposide followed by consolidation chemotherapy in patients with unresectable stage III nonsquamous NSCLC. Both regimens were equivalent in terms of survival, but the cisplatin/pemetrexed regimen was associated with less neutropenia (24.4% vs. 44.5%; \(P < .001\)) and fewer grade 3 to 4 adverse events (64.0% vs. 76.8%; \(P = .001\)). The NCCN NSCLC Panel recently deleted the cisplatin/etoposide consolidation regimen based on the PROCLAIM trial. In addition, the NCCN NSCLC Panel clarified that the cisplatin/pemetrexed and carboplatin/paclitaxel regimens may be followed by consolidation chemotherapy alone for patients receiving definitive chemoradiation.

**Surveillance**

Because recurrence is common after treatment for NSCLC, surveillance with history and physical (H&P) and chest CT (with or without contrast) is recommended in the NCCN Guidelines. Data from randomized phase 3 trials are not available to clarify surveillance recommendations; therefore, the most appropriate schedules are controversial. The surveillance guidelines were recently revised by polling the NCCN NSCLC Panel regarding their practice patterns. Details regarding the specific surveillance schedules for patients with no clinical or radiographic evidence of disease after completion of definitive therapy are outlined in the algorithm based on stage (see Surveillance in the NCCN Guidelines for NSCLC). A chest CT scan with (or without) contrast and an H&P are recommended for the initial surveillance schedules (2–5 years) followed by an annual low-dose non-contrast–enhanced CT and an H&P. Patients treated with chemotherapy with (or without) RT who have residual abnormalities may require more frequent imaging.

It is important to note that the surveillance recommendations for NSCLC are different from the screening recommendations for individuals at high risk for lung cancer (see the NCCN Guidelines for Lung Cancer Screening). Data show that low-dose CT screening decreased the mortality from lung cancer; low-dose CT may be beneficial for identifying recurrences. FDG PET/CT or brain MRI is not routinely recommended for routine surveillance in patients without symptoms. But, PET may be useful for assessing CT scans that appear to show malignant neoplasms but may be radiation fibrosis, atelectasis, or other benign conditions. Areas previously treated with RT may remain FDG avid for up to 2 years; therefore, histologic confirmation of apparent “recurrent” disease is needed. Information about smoking cessation (eg, advice, counseling, therapy) should be provided for patients undergoing surveillance to improve their quality of life.

The NCCN Guidelines include information about the long-term follow-up care of NSCLC survivors (see Cancer Survivorship Care in the NCCN Guidelines for NSCLC). These recommendations include guidelines for routine cancer surveillance, immunizations, health monitoring, counseling for wellness and health promotion, and cancer screening. An analysis suggests that patients who survive lung cancer have a high symptom burden 1 year after diagnosis and therefore need management after treatment.

**Treatment of Recurrences and Distant Metastases**

Recurrences are subdivided into locoregional recurrences and distant metastases. Management of locoregional recurrences or symptomatic
local disease (eg, endobronchial obstruction, mediastinal lymph node recurrence, superior vena cava [SVC] obstructions, severe hemoptysis) is described in the NCCN Guidelines (see Therapy for Recurrence and Metastasis in the NCCN Guidelines for NSCLC).\textsuperscript{12} For the 2019 update (Version 1), the NCCN NSCLC Panel clarified the recommended treatment for SVC obstruction and severe hemoptysis. For example, an SVC stent may be used with either concurrent chemoradiation or RT to treat SVC obstruction. For patients with endobronchial obstruction, relieving airway obstruction may increase survival, especially in patients who are severely compromised, and may improve the quality of life.\textsuperscript{893}

After treatment for the locoregional recurrence, observation or systemic therapy (category 2B for systemic therapy) is recommended if disseminated disease is not evident. Systemic therapy is recommended for disseminated disease. The type of systemic therapy depends on the histologic type, whether genetic alterations are present that can be treated with targeted therapy, and PS (see Systemic Therapy for Advanced or Metastatic Disease in the NCCN Guidelines for NSCLC). The NCCN NSCLC Panel recommends (category 2A) response assessment after 2 cycles of systemic therapy, then after every 2 to 4 cycles of therapy or when clinically indicated; assessment is done using CT with (or without contrast) of known sites of disease.\textsuperscript{205,894-896}

Management of distant metastases (eg, localized symptoms; bone, limited, diffuse brain, or disseminated metastases) is described in the NCCN Guidelines (see Therapy for Recurrence and Metastasis in the NCCN Guidelines for NSCLC). Palliation of symptoms throughout the disease course can be achieved with external-beam RT for distant metastases with localized symptoms, diffuse brain metastases, or bone metastases (bisphosphonate or denosumab therapy can be considered).\textsuperscript{381,471,897} For patients at risk of fracture in weight-bearing bone, orthopedic stabilization and palliative RT are recommended.

Denosumab or intravenous bisphosphonate therapy can be considered in patients with bone metastases to decrease bone complications (eg, decrease pain, delay skeletal-related events).\textsuperscript{146,906-909} In patients with NSCLC who have bone metastases, data suggest that denosumab increases median overall survival when compared with zoledronic acid (9.5 vs. 8 months).\textsuperscript{910} Denosumab and bisphosphonate therapy can be associated with severe hypocalcemia; patients with hypoparathyroidism and vitamin D deficiency are at increased risk for hypocalcemia. The FDA has approved the use of zoledronic acid and denosumab in patients with bone metastases from solid tumors.\textsuperscript{911,912}

For patients with recurrent and metastatic disease, the NCCN Guidelines recommend that histologic subtype should be determined before therapy so that the best treatment can be selected (see Metastatic Disease: Histologic Subtype in the NCCN Guidelines for NSCLC).\textsuperscript{252} In addition, biomarker testing for genetic alterations (ie, oncogenic driver events) is recommended in patients with NSCLC, because targeted therapy has
been shown to decrease tumor burden, decrease symptoms, and dramatically improve the quality of life for patients with specific genetic alterations. The number of available targeted agents is increasing. Several targeted agents have category 1 recommendations for first-line therapy based on phase 3 randomized trials such as erlotinib, gefitinib, afatinib, osimertinib, dacomitinib, alectinib, ceritinib, brigatinib, and crizotinib. Additional targeted therapies for patients with other genetic alterations are also recommended, although there is less evidence for these agents and they have not been FDA approved for lung cancer (see Emerging Biomarkers to Identify Novel Therapies for Patients With Metastatic NSCLC in the NCCN Guidelines for NSCLC). Targeted therapies—such as ceritinib, alectinib, brigatinib, and osimertinib—are recommended as subsequent therapies (if not previously given) for patients with the indicated genetic alterations whose disease becomes resistant to first-line targeted therapies; other targeted therapies are being investigated for resistance.

Biomarker testing for genetic alterations is recommended in the NCCN Guidelines. Recently, the NCCN NSCLC Panel added a section describing the details of biomarker testing (see Principles of Molecular and Biomarker Analysis in the NCCN Guidelines for NSCLC). It is important to note that 1) several different tests may be used to identify the same biomarker, including FDA-approved biomarker tests and validated laboratory tests done in CLIA-approved laboratories; and 2) biomarker testing is rapidly changing and improving. EGFR mutation testing (category 1) is recommended in patients with nonsquamous NSCLC (ie, adenocarcinoma, large cell carcinoma) or NSCLC NOS, because EGFR TKIs are recommended for patients who are positive for sensitizing EGFR mutations (see EGFR Mutation Positive/First-Line Therapy in the NCCN Guidelines for NSCLC). Testing for ALK rearrangements (category 2A) is also recommended in patients with nonsquamous NSCLC, because ALK inhibitors are recommended for patients who are positive for ALK rearrangements. The NCCN NSCLC Panel also recommends testing for ROS1 rearrangements (category 2A). Testing for ROS1 has typically been done using FISH; a validated NGS platform that can detect this gene fusion may also be used. The NCCN NSCLC Panel recommends that EGFR and BRAF mutation testing be done as part of broad molecular profiling (eg, multiplex mutation screening assays or NGS). Testing for ALK gene rearrangements can be done with FISH or with NGS if the platform is validated and can identify gene fusions. The NCCN NSCLC Panel also recommends upfront PD-L1 expression testing (category 2A) before first-line therapy in patients with metastatic NSCLC to assess whether patients are candidates for pembrolizumab (see Pembrolizumab in this Discussion).

The following targeted agents are recommended (category 2A) for patients with specific genetic alterations: 1) crizotinib (for high-level MET amplification or METex14 mutation); 2) cabozantinib or vandetanib (for RET rearrangements); and 3) ado-trastuzumab for HER2 mutations. The NCCN NSCLC Panel recommends crizotinib for high-level MET amplification or METex14 mutation based on data from several studies. The NCCN NSCLC Panel recommends vandetanib (category 2A) for RET rearrangements based on data from a phase 2 study in 18 patients who had received 2 or more previous chemotherapy regimens. The overall survival was 11.6 months and the PFS was 4.5 months. Partial remission (18%) was reported in 3 patients; stable disease was reported in another 8 patients. The disease control rate was 65%. Six (33%) patients died within 3 months of enrollment of the study due to rapid tumor progression. The recommendation for cabozantinib for RET rearrangements is based on data from a phase II study in 26 patients. The overall response rate was 28% (95% CI, 12%–49%). Many patients (19 [73%]) needed dose reductions because of adverse events. The most common grade 3 adverse events included lipase
elevation (4 patients [15%]), increased ALT (2 [8%]), decreased platelet count (2 [8%]), and hypophosphatemia (2 [8%]).

The NCCN NSCLC Panel recommends ado-trastuzumab emtansine (category 2A) for patients with HER2 mutations based on results from a phase 2 basket trial. The partial response rate was 44% (95% CI, 22%–69%). The median PFS was 5 months (95% CI, 3–9). Minor toxicities (grade 1–2) included infusion reactions, thrombocytopenia, and transaminitis; no treatment-related deaths were reported. Patients (n=18) were mostly women (72%) and nonsmokers, and all had adenocarcinomas. The NCCN NSCLC Panel does not recommend single-agent therapy with trastuzumab or afatinib (both for HER2 mutations), because response rates are lower and treatment is less effective when these agents are used for patients with HER2 mutations.

As previously mentioned, recommendations from an international panel suggest that general histologic categories be avoided (eg, NSCLC), because more effective treatment can be selected when the histology is known. Patients with pure squamous cell carcinoma do not seem to have ALK rearrangements, ROS1 rearrangements, sensitizing EGFR mutations, or BRAF mutations; therefore, routine testing is not recommended in these patients. However, testing for ALK rearrangements, ROS1 rearrangements, BRAF mutations, or EGFR mutations can be considered in patients with squamous cell carcinomas whose histology was determined using small biopsy specimens or mixed histology specimens. Testing for EGFR mutations or ALK rearrangements can also be considered in patients who never smoked. Treatment recommendations and eligibility criteria are described in the NCCN Guidelines for patients with nonsquamous NSCLC (or NSCLC NOS) with negative or unknown test results for ALK rearrangements or sensitizing EGFR mutations and with PD-L1 expression less than 1% or unknown.

Treatment recommendations and eligibility criteria for patients with squamous cell carcinoma are also described in the NCCN Guidelines. These recommendations are briefly summarized in the following paragraphs. Data supporting these recommendations are described in the following section (see Trial Data in this Discussion).

Chemotherapy/immunotherapy regimens are now recommended for patients without genetic alterations (see Systemic Therapy for Advanced or Metastatic Disease in the NCCN Guidelines for NSCLC). Single-agent targeted therapy is recommended for patients with ALK or ROS1 rearrangements, sensitizing EGFR mutations, or other driver mutations (see Emerging Biomarkers to Identify Novel Therapies for Patients With Metastatic NSCLC in the NCCN Guidelines for NSCLC). Pembrolizumab is recommended (category 1, preferred) as first-line monotherapy for patients with PD-L1 expression of 50% or more.

Chemotherapy/immunotherapy regimens, such as pembrolizumab/carboplatin (or cisplatin)/pemetrexed, are recommended (category 1, preferred) for patients with nonsquamous NSCLC and negative or unknown test results for ALK rearrangements or sensitizing EGFR mutations and with PD-L1 expression less than 50% or unknown (also known as wild-type) (see Systemic Therapy for Advanced or Metastatic Disease in the NCCN Guidelines for NSCLC, the NCCN Drugs & Biologics Compendium [NCCN Compendium®] for NSCLC, and the NCCN Guidelines With Evidence Blocks™ for NSCLC). 252

For patients with metastatic NSCLC and contraindications to pembrolizumab, other chemotherapy options are recommended (such as carboplatin/paclitaxel), although some regimens may be more appropriate for certain patients, depending on histology, PS, and other factors (see Trial Data in this Discussion, Systemic Therapy for Advanced or Metastatic Disease in the NCCN Guidelines for NSCLC, the NCCN Compendium® for NSCLC, and the NCCN Guidelines With Evidence Blocks™ for NSCLC). 252
Bevacizumab/chemotherapy is an option if eligibility criteria are met for patients with nonsquamous NSCLC and negative or unknown test results for ALK rearrangements or sensitizing EGFR mutations and with PD-L1 expression less than 1% or unknown. Previously, patients with brain metastases were excluded from receiving bevacizumab because of concerns about CNS hemorrhage; however, data suggest that bevacizumab can be used in patients with treated CNS metastases. A phase 3 randomized trial in elderly patients (70–89 years) with advanced NSCLC reported that combined therapy with weekly paclitaxel and monthly carboplatin improved survival when compared with single-agent therapy using either gemcitabine or vinorelbine (10.3 vs. 6.2 months). Systemic therapy for elderly patients with advanced NSCLC needs to be carefully selected to avoid adverse reactions. The NCCN NSCLC Panel previously revised the lists of recommended doublet and single-agent cytotoxic therapy regimens for patients with nonsquamous NSCLC or NSCLC NOS—who are negative or unknown for mutations, rearrangements, or PD-L1 expression—by deleting regimens that are rarely used in the United States. Deleted regimens include carboplatin/vinorelbine, cisplatin/vinorelbine, etoposide, irinotecan, and vinorelbine.

For patients with metastatic squamous cell NSCLC and negative or unknown test results for mutations, rearrangements, or PD-L1 expression, chemotherapy/immunotherapy regimens—such as pembrolizumab/carboplatin/paclitaxel or albumin-bound paclitaxel—are recommended (category 1, preferred) as of the 2019 update. For patients with contraindications to pembrolizumab, cisplatin/gemcitabine (category 1) is a recommended doublet option for patients with squamous cell carcinoma. Carboplatin/paclitaxel, carboplatin/gemcitabine (category 1 for both), and other regimens listed in the NSCLC algorithm are also recommended (see Systemic Therapy for Advanced or Metastatic Disease in the NCCN Guidelines for NSCLC, the NCCN Compendium® for NSCLC, and the NCCN Guidelines With Evidence Blocks™ for NSCLC). The NCCN NSCLC Panel previously revised the lists of recommended doublet cytotoxic therapy regimens by deleting regimens that are rarely used for patients with metastatic squamous cell carcinoma NSCLC and negative or unknown test results for ALK rearrangements or sensitizing EGFR mutations and with PD-L1 expression less than 1% or unknown. Deleted regimens include carboplatin/etoposide, carboplatin/vinorelbine, cisplatin/vinorelbine, cisplatin/gemcitabine/necitumumab, etoposide, irinotecan, and vinorelbine. Regimens containing pemetrexed or bevacizumab are not recommended for squamous cell carcinoma. Currently, there are fewer treatment options for patients with squamous cell carcinoma when compared with nonsquamous NSCLC. Research is ongoing to find newer options.

**Trial Data**

Data show that platinum-based combination therapy is superior to best supportive care for patients with advanced, incurable disease. Cisplatin or carboplatin have been proven effective in combination with many of the following agents: docetaxel, etoposide, gemcitabine, paclitaxel (and albumin-bound paclitaxel), pemetrexed, and vinorelbine (see Systemic Therapy for Advanced or Metastatic Disease in the NCCN Guidelines for NSCLC). Carboplatin-based regimens are often used for patients with comorbidities or those who cannot tolerate cisplatin. Non-platinum regimens (eg, gemcitabine/docetaxel, gemcitabine/vinorelbine) are reasonable alternatives, because data show they are active and less toxic than platinum-based regimens.

In a phase 2/3 trial (ECOG 4599), 878 patients were randomly assigned to either 1) bevacizumab in combination with paclitaxel/carboplatin; or 2) paclitaxel/carboplatin alone. Both regimens were well tolerated with selected toxicities. Patients receiving bevacizumab/paclitaxel/carboplatin showed an improved median survival (12.3 vs. 10.3 months, P = .003).
when compared to patients receiving paclitaxel/carboplatin alone.251 The overall 1-year and 2-year survival was 51% versus 44% and 23% versus 15%, respectively, in favor of the bevacizumab/paclitaxel/carboplatin arm.251 More significant toxicities were observed with bevacizumab/paclitaxel/carboplatin compared to paclitaxel/carboplatin (grade 4 neutropenia: 25.5% vs. 16.8%; grade 5 hemoptysis: 1.2% vs. 0%; and grade 3 hypertension: 6.8% vs. 0.5%). Treatment-related deaths were more common with bevacizumab/paclitaxel/carboplatin (15 patients) than with paclitaxel/carboplatin (2 patients) (P = .001). An analysis of ECOG 4599 found that patients with adenocarcinoma histology receiving bevacizumab/paclitaxel/carboplatin had improved survival compared with chemotherapy alone (14.2 vs. 10.3 months).936 A trial (AVAiL) comparing cisplatin/gemcitabine with (or without) bevacizumab did not show an increase in survival with the addition of bevacizumab.945,946

A noninferiority trial in 1725 patients with advanced NSCLC (either stage IIIb or IV; most were stage IV) assessed cisplatin/gemcitabine compared with cisplatin/pemetrexed.252 Patients with either adenocarcinoma or large cell carcinoma (ie, nonsquamous NSCLC) had improved survival with cisplatin/pemetrexed (adenocarcinoma: 12.6 vs. 10.9 months). Patients with squamous cell carcinoma had improved survival with the cisplatin/gemcitabine regimen (10.8 vs. 9.4 months). When compared with the cisplatin/gemcitabine regimen, the cisplatin/pemetrexed regimen had significantly lower rates of grade 3 or 4 neutropenia, anemia, and thrombocytopenia (P ≤ .001); febrile neutropenia (P = .002); and alopecia (P < .001). Treatment-related deaths were similar for both regimens (cisplatin/pemetrexed, 9 patients [1.0%]; cisplatin/gemcitabine, 6 patients [0.7%]). An analysis of three phase 3 trials confirmed that pemetrexed improves survival for patients with nonsquamous NSCLC in first-line, subsequent, and maintenance therapy.947

### Number of Cycles of First-Line Systemic Therapy

Patients receiving first-line systemic therapy for advanced disease should be evaluated for tumor response with a CT scan. Response assessment should occur after 2 cycles and then every 2 to 4 cycles using CT of known sites of disease (with or without contrast) or when clinically indicated.205,894-896 Approximately 25% of patients show disease progression after the initial cycle of chemotherapy; subsequent therapy is recommended for these patients (see the NCCN Guidelines for NSCLC). Patients with responsive or stable disease can continue to receive a total of 4 to 6 cycles of systemic therapy.596,792,948 The NCCN Guidelines do not recommend continuing chemotherapy beyond 4 to 6 cycles.

Data from the PARAMOUNT trial suggest that 4 cycles of platinum-based therapy is not optimal;784 tumors can shrink between 4 to 6 cycles of chemotherapy. However, patients may not be able to tolerate more than 4 cycles of chemotherapy, and most of the maintenance trials used only 4 cycles of chemotherapy.852 A meta-analysis suggests that continuing the initial regimen beyond 4 to 6 cycles is associated with increased PFS; patients have more adverse events.949 A phase 3 randomized trial suggested that continuing chemotherapy beyond 4 to 6 cycles is not beneficial; however, many patients assigned to a longer duration of therapy did not receive the planned number of cycles.791,792 In this phase 3 trial, taxane-based regimens were used and patients had increasing neurotoxicity as more cycles were used.792

Many patients with adenocarcinoma receive pemetrexed-based regimens and not taxane-based regimens. Pemetrexed-based regimens are less toxic than taxane-based regimens. Thus, data suggesting that more than 6 cycles of first-line chemotherapy are not appropriate may only apply to taxane-based regimens.852 Studies report that 60% of patients were able to receive 6 cycles of pemetrexed-based chemotherapy (and had a low incidence of toxicity), whereas only 42% were able to receive more than 5
cycles of taxane-based chemotherapy and often stopped therapy because of neurotoxicity.782,792

**Maintenance Therapy**

For patients with nonsquamous NSCLC who are negative or have unknown rearrangements, mutations, or PD-L1 expression, maintenance therapy is another option for those with responsive or stable disease after first-line systemic therapy (see the NCCN Guidelines for NSCLC). Continuation maintenance therapy includes bevacizumab (category 1), pemetrexed (category 1), bevacizumab/pemetrexed (category 2A), or gemcitabine (category 2B) (see the NCCN Guidelines for NSCLC).251,654,754,784,786,788,789 Switch maintenance therapy for these patients includes pemetrexed (category 2A).788,794,795 Recently, the NCCN NSCLC Panel revised the recommendation for switch maintenance therapy with pemetrexed to category 2A (from 2B) based on clinical experience.

A phase 3 randomized trial (n = 663) assessed the effect of best supportive care with (or without) switch maintenance pemetrexed in patients with advanced NSCLC who had received platinum-based chemotherapy but had not progressed.795 In patients with nonsquamous NSCLC, overall survival was 13.4 months (95% CI, 11.9–15.9) with pemetrexed compared with 10.6 months (8.7–12.0) with placebo (HR, 0.50; 95% CI, 0.42–0.61; P < .0001). Close observation is another option. Maintenance therapy is discussed in greater detail earlier in this Discussion (see Combined Modality Therapy: Maintenance Therapy).

The NCCN NSCLC Panel recently deleted the recommendation for erlotinib as switch maintenance therapy (and as subsequent therapy) for patients with nonsquamous NSCLC and PS 0 to 2 but without EGFR mutations based on results from a randomized trial (IUNO) and revised indication by the FDA.797 The data showed that overall survival and PFS were not improved in patients receiving erlotinib when compared with placebo. For patients with squamous cell carcinoma, gemcitabine (category 2B) is recommended as continuation maintenance therapy (see the NCCN Guidelines for NSCLC).789,794 Docetaxel is recommended (category 2B) as switch maintenance therapy for these patients. Close observation is a category 2A option. As previously mentioned, a phase 3 randomized trial compared using maintenance therapy with either gemcitabine or erlotinib after initial cytotoxic therapy with cisplatin-gemcitabine. Continuation maintenance therapy with single-agent gemcitabine increased PFS to a greater extent (3.8 months) than switch maintenance therapy with erlotinib (2.9 months) when compared with observation (1.9 months).788,789 The benefits of maintenance therapy were very slight; therefore, the recommendation is only category 2B for maintenance therapy with gemcitabine. A phase 3 trial assessed switch maintenance therapy with docetaxel given either immediately after chemotherapy or delayed until progression.799 Switch maintenance therapy with docetaxel is a category 2B recommendation in the NCCN Guidelines, because many patients in the delayed chemotherapy arm did not receive docetaxel.950

**Continuation of Targeted Therapy After Progression on Initial Therapy**

Patients may continue to derive benefit from EGFR TKIs or ALK inhibitors after disease progression on first-line therapy; discontinuation of these TKIs leads to more rapid progression of disease (symptoms, tumor size, FDG-avidity on PET scan).951 This strategy mirrors the experience in other oncogene-addicted cancers, such as ALK inhibitors.952 Because of previous restrictions on the use of gefitinib, erlotinib was commonly used in the United States in patients with sensitizing EGFR mutations. Gefitinib was re-approved by the FDA based on a phase 4 study and is available in the United States.145 After development of acquired resistance in patients with lung adenocarcinoma and sensitizing EGFR mutations, erlotinib,
gefitinib, afatinib, dacomitinib, or osimertinib may be continued, but osimertinib as second-line therapy is also an option for select patients; local therapy should be considered (eg, SRS to brain metastases or other sites, SABR for thoracic disease).544,864,865,953,954

Accumulating data suggest how cancers become resistant to EGFR inhibitors.955 The most common known mechanism is the acquisition of T790M (which is a secondary mutation in EGFR), which renders the kinase resistant to erlotinib, gefitinib, dacomitinib, or afatinib.956,957 Therefore, if patients are T790M positive, osimertinib is recommended (category 1) and erlotinib, gefitinib, dacomitinib, or afatinib are discontinued. Amplification of the MET oncogene is another validated resistance mechanism. To overcome resistance, EGFR must still be inhibited. In the case of MET amplification, new inhibitors must be added to the EGFR inhibitor; EGFR inhibition is still required to induce remission. Furthermore, data by Riely et al show that when cancers start to progress, which were once sensitive to EGFR inhibitors, discontinuation of the EGFR TKI can lead to a much more accelerated progression of the cancer.951,958 Thus, continuing EGFR TKIs is beneficial in many patients even after they develop resistance to EGFR TKIs.954

The NCCN NSCLC Panel recommends continuing erlotinib, gefitinib, afatinib, dacomitinib, or osimertinib and considering local therapy in patients with asymptomatic progression; however, treatment varies for patients with symptomatic progression (see Sensitizing EGFR Mutation Positive: Subsequent Therapy in the NCCN Guidelines for NSCLC).924,953,959-961 Osimertinib is recommended (category 1) for patients with symptomatic brain metastases and T790M who have progressed on erlotinib, gefitinib, dacomitinib, or afatinib.208 Another option is to continue use of erlotinib, gefitinib, dacomitinib, or afatinib for these patients with symptomatic brain metastases; additional therapy may be added or substituted (eg, local therapy, systemic therapy). First-line systemic therapy options are recommended for patients with multiple symptomatic lesions who are negative for T790M; osimertinib is recommended (category 1) as subsequent therapy for patients positive for T790M who have progressed on erlotinib, gefitinib, dacomitinib, or afatinib. After progression on osimertinib, patients with sensitizing EGFR mutations may continue to derive benefit from osimertinib; other options are also recommended [see Second-Line and Beyond (Subsequent) Systemic Therapy in this Discussion]. After progression on alectinib, brigatinib, or ceritinib, patients with ALK rearrangements may continue to derive benefit from these agents; other options are also recommended [see Second-Line and Beyond (Subsequent) Systemic Therapy in this Discussion].

Second-Line and Beyond (Subsequent) Systemic Therapy

The phrase subsequent therapy was recently substituted for the terms second-line, third-line, and beyond systemic therapy, because the line of therapy may vary depending on previous treatment with targeted agents. Subsequent systemic therapy regimens for patients who have disease progression during or after first-line therapy are described in the NSCLC algorithm and depend on the specific genetic alteration, the histologic subtype, and whether the patient has symptoms (see the NCCN Guidelines for NSCLC).962-971 The NCCN NSCLC Panel recommends response assessment of known sites of disease with CT (with contrast) every 6 to 12 weeks in patients receiving subsequent therapy. Note that traditional RECIST response criteria (1.1) are used to assess response for most types of systemic therapy, but different response criteria may be useful for assessing response in patients receiving immunotherapy.205,894,896,972,973

The NCCN NSCLC Panel recommends immune checkpoint inhibitors as preferred agents for subsequent therapy in patients with metastatic NSCLC based on improved survival rates, longer duration of response,
and fewer adverse events when compared with cytotoxic chemotherapy (see Nivolumab, Pembrolizumab, and Atezolizumab in this Discussion).

Human immune-checkpoint–inhibitor antibodies inhibit the PD-1 receptor or PD-L1, which improves antitumor immunity; PD-1 receptors are expressed on activated cytotoxic T cells. The NCCN NSCLC Panel recommends nivolumab (category 1) as subsequent therapy for patients with metastatic nonsquamous or squamous NSCLC based on phase 3 randomized trials (CheckMate 017 and CheckMate 057) and FDA approvals.

The NCCN NSCLC Panel recommends pembrolizumab (category 1) as subsequent therapy for patients with metastatic nonsquamous or squamous NSCLC and PD-L1 expression based on a phase 2/3 randomized trial (KEYNOTE-010), KEYNOTE-001 trial, and FDA approval. The NCCN NSCLC Panel also recommends atezolizumab (category 1) as subsequent therapy for patients with metastatic nonsquamous or squamous NSCLC based on a phase 3 randomized trial (OAK), data from a phase 2 trial (POPLAR), and FDA approval.

The NCCN NSCLC Panel recommends osimertinib (category 1) as subsequent therapy for patients with metastatic nonsquamous or squamous NSCLC who have progressed on erlotinib, gefitinib, dacomitinib, or afatinib therapy based on recent data and on the FDA approval (see Osimertinib in this Discussion).

For patients with sensitizing EGFR mutations who progress during or after first-line erlotinib, afatinib, gefitinib, dacomitinib, or osimertinib therapy, recommended subsequent therapy depends on whether the progression is asymptomatic or symptomatic and includes: 1) considering local therapy; 2) continuing erlotinib, afatinib, gefitinib, dacomitinib, or osimertinib; 3) taking osimertinib if not previously given and T790M positive; or 4) taking a first-line systemic therapy regimen for nonsquamous NSCLC (such as cisplatin/pemetrexed). The NCCN NSCLC Panel recommends osimertinib (category 1) for patients with T790M who have brain metastases and have progressed on erlotinib, afatinib, dacomitinib, or gefitinib.

Data suggest that an afatinib/cetuximab regimen may be useful for patients who have progressed after receiving erlotinib, afatinib, or gefitinib and after chemotherapy. Patients with T790M-positive and T790M-negative tumors had a similar response rate to an afatinib/cetuximab regimen (32% vs. 25%; P = .341). The NCCN NSCLC Panel recommends (category 2A) considering an afatinib/cetuximab regimen for patients who have progressed after receiving erlotinib, afatinib, dacomitinib, or gefitinib and chemotherapy based on these data.

The NCCN NSCLC Panel recently added a new subsequent therapy algorithm for patients with advanced NSCLC and sensitizing EGFR mutations who progress during or after first-line therapy with osimertinib. Recommended subsequent therapy depends on whether the progression is asymptomatic or symptomatic and includes: 1) considering local therapy; and/or 2) continuing osimertinib or switching to a first-line systemic therapy regimen for nonsquamous NSCLC (such as cisplatin/pemetrexed). There are no data to support using erlotinib, gefitinib, dacomitinib, or afatinib after progression on osimertinib.

Among patients with sensitizing EFR mutations, no improvement in overall survival has been noted in the phase 3 trials assessing subsequent therapy with pembrolizumab, nivolumab, or atezolizumab compared to docetaxel, but there were not enough patients with these mutations to determine whether there were statistically significant differences. Immunotherapy was not worse than chemotherapy and was better tolerated. In the phase 3 trials for pembrolizumab, nivolumab, or atezolizumab versus docetaxel as subsequent therapy for patients with metastatic NSCLC, subset analyses were done in patients with EGFR mutations to determine the best subsequent therapy. The HRs for overall survival do not favor docetaxel over nivolumab (HR, 1.18; CI, 0.69–2.0), pembrolizumab (HR, 0.88; CI, 0.45–1.7), or atezolizumab (HR, 1.24; CI, 0.7–2.2); the CIs for the HRs are wide.
probably because there were so few patients with EGFR mutations. The HRs for PFS do favor docetaxel for patients with EGFR mutations when compared with either pembrolizumab (HR, 1.79; CI, 0.94–3.42) or nivolumab (HR, 1.46; CI, 0.90–2.37). But again, the CIs are wide. The evidence is weak for recommending docetaxel, pembrolizumab, nivolumab, or atezolizumab as subsequent therapy for patients with EGFR mutations. Data suggest that patients with EGFR mutations or ALK rearrangements have a low response rate to PD-1 or PD-L1 inhibitors when compared with patients without these genetic alterations (response rate, 3.6% vs. 23%, respectively). Therefore, the NCCN NSCLC Panel recently deleted the recommendation for pembrolizumab as subsequent therapy for patients with PD-L1 expression of 50% or more and genetic alterations such as EGFR mutations or ALK rearrangements.

For the 2019 update (Version 2), the NCCN NSCLC Panel now recommends lorlatinib (category 2A) as a subsequent therapy option for select patients with ALK-positive NSCLC who have progressed after treatment with ALK inhibitors (see Lorlatinib in this Discussion). For patients with ALK rearrangements who progress during or after first-line targeted therapy, recommended subsequent therapy depends on whether the progression is asymptomatic or symptomatic and includes: 1) considering local therapy (eg, SABR, SRS, surgery); 2) continuing alectinib, brigatinib, crizotinib, or ceritinib; 3) taking alectinib, brigatinib, or ceritinib (if all were not previously given) or lorlatinib; or 4) taking a first-line systemic therapy regimen for nonsquamous NSCLC. After further progression on subsequent targeted therapy, options include: 1) lorlatinib; or 2) first-line combination chemotherapy options for NSCLC (eg, carboplatin/paclitaxel), which are recommended for patients with PS of 0 to 1. Other chemotherapy options are also recommended for patients with PS 2, such as docetaxel (see Systemic Therapy for Advanced or Metastatic Disease in the NCCN Guidelines for NSCLC). Patients with ALK-positive NSCLC and very high PD-L1 expression do not respond to pembrolizumab. In addition, those with MET exon 14 mutations and high PD-L1 expression also do not respond to immunotherapy. For the 2019 update (Version 2), the NCCN NSCLC Panel also recommends lorlatinib (category 2A) as a subsequent therapy option for select patients with ROS1-positive NSCLC who have progressed after treatment with crizotinib or ceritinib. Most patients with NSCLC do not have ALK rearrangements, ROS1 rearrangements, BRAF V600E mutations, or sensitizing EGFR mutations. For patients with all histologic subtypes and PS of 0 to 2 but without these genetic alterations who have disease progression during or after initial cytotoxic therapy, recommended subsequent systemic therapy options include immunotherapy (nivolumab, pembrolizumab, or atezolizumab [category 1 for all] if any were not previously given) or chemotherapy (docetaxel with or without ramucirumab, or gemcitabine if not already given; pemetrexed is recommended for patients with nonsquamous NSCLC) if not already given. The NCCN NSCLC Panel recommends immune checkpoint inhibitors—nivolumab, pembrolizumab, or atezolizumab if not already given—as preferred options for subsequent therapy for all histologic subtypes based on improved survival rates, longer duration of response, and fewer adverse events when compared with cytotoxic chemotherapy (see Nivolumab, Pembrolizumab, and Atezolizumab in this Discussion). Immunotherapy is superior to docetaxel; however, some patients cannot tolerate immunotherapy. Ramucirumab/docetaxel is an option for all histologic subtypes for subsequent therapy based on a phase 3 randomized trial (see Ramucirumab in this Discussion). Docetaxel has been proven superior to best supportive care, vinorelbine, or ifosfamide with improved survival and quality of life. When compared with docetaxel, pemetrexed has similar median survival but less toxicity.
Pemetrexed is recommended in patients with nonsquamous NSCLC. Docetaxel is recommended for patients with wild-type EGFR tumors based on 2 randomized trials comparing erlotinib versus docetaxel. In patients with PS of 3 to 4, best supportive care is recommended (see the NCCN Guidelines for NSCLC). Patients often have a limited response to subsequent chemotherapy other than immune checkpoint inhibitors, although chemotherapy may serve a useful palliative role.

The NCCN NSCLC Panel recently deleted the recommendation for erlotinib as subsequent therapy (and as switch maintenance therapy) for patients with nonsquamous NSCLC and PS of 0 to 2 but without EGFR mutations based on results from a randomized trial (IUNO) and revised indication by the FDA. Data showed that overall survival and PFS were not improved in patients receiving erlotinib when compared with placebo. Recently, the NCCN NSCLC Panel deleted erlotinib as an option for subsequent therapy for patients with squamous cell NSCLC based on a study comparing afatinib with erlotinib; this study was statistically significant but not clinically significant. Overall survival was slightly better in the afatinib group than in the erlotinib group (median overall survival, 7.9 months [95% CI, 7.2–8.7] vs. 6.8 months [95% CI, 5.9–7.8]; HR, 0.81 [95% CI, 0.69–0.95], P=.0077); however, almost 60% of patients in each arm had grade 3 or higher adverse events. In contrast, the median overall survival was 9.2 months with nivolumab compared with 6.0 months for docetaxel for patients with squamous cell NSCLC. In addition, only 7% of patients receiving nivolumab had grade 3 or higher adverse events. Erlotinib and afatinib are not recommended as second-line therapy for squamous cell carcinoma based on a phase 3 randomized trial showing low response rates; they are less efficacious and safe compared to other available options.

Doublet chemotherapy options used for initial cytotoxic therapy are recommended for patients with metastatic NSCLC (eg, carboplatin/paclitaxel) and genetic alterations who progress with symptomatic systemic multiple lesions after first-line targeted therapy. Recent data (IMPRESS) indicate that chemotherapy should be used alone and not be combined with EGFR inhibitors such as gefitinib in patients who have progressed on gefitinib. Erlotinib, gefitinib, afatinib, dacomitinib, or osimertinib may be continued in patients with sensitizing EGFR mutations who have progressed after first-line therapy, depending on the type of progression.

Subsequent therapy is recommended after second disease progression in patients with advanced NSCLC and a PS of 0 to 2 if the following agents have not already been given: 1) immune checkpoint inhibitors including nivolumab, pembrolizumab, and atezolizumab if none have been previously given (all are category 2A); 2) docetaxel with or without ramucirumab (category 2B for both); 3) gemcitabine (category 2B); or 4) pemetrexed (nonsquamous only) (category 2B). For patients with metastatic NSCLC who have progressed after first-line therapy with pembrolizumab, platinum-based doublet therapy is recommended (eg, carboplatin/paclitaxel). For patients with metastatic NSCLC who have progressed after first-line therapy with PD-1/PD-L1 inhibitors/chemotherapy, subsequent therapy with docetaxel (with or without ramucirumab), pemetrexed (for nonsquamous only), or...
gemcitabine is recommended. Clinical trials are also recommended in these settings.

Summary

The NCCN Guidelines for NSCLC are updated at least once a year by the NCCN NSCLC Panel; there were 6 updates in 2018. The Summary of the Guidelines Updates describes the most recent revisions to the algorithms, which have been incorporated into this updated Discussion text (see the NCCN Guidelines for NSCLC). A brief summary of some of the recent updates is as follows: For the 2019 update (Version 1), the NCCN NSCLC Panel recommends several new regimens for patients with metastatic NSCLC, including: 1) dacomitinib (category 1) as a first-line treatment option for sensitizing EGFR-mutation–positive disease; 2) brigatinib (category 1) as a first-line treatment option for ALK-positive disease; and 3) nivolumab with or without ipilimumab (category 2A) as first-line therapy for high TMB. For the Version 2 update, lorlatinib (category 2A) is recommended as a subsequent therapy option for certain patients with ALK-positive or ROS1-positive NSCLC who have progressed after treatment with ALK inhibitors. For the Version 3 update, larotrectinib is now recommended as a first-line therapy option for patients with NTRK gene–fusion positive metastatic NSCLC.

In addition, several regimens are now preferred as first-line therapy for patients with metastatic NSCLC, including: 1) osimertinib monotherapy for sensitizing EGFR mutation-positive disease (preferred, category 1); 2) pembrolizumab monotherapy (preferred, category 1) for patients with PD-L1 expression levels of 50% or more and with negative or unknown test results for EGFR mutations or ALK rearrangements, regardless of histology; 3) pembrolizumab/carboplatin (or cisplatin)/pemetrexed (preferred, category 1) for patients with nonsquamous NSCLC, negative or unknown test results for EGFR mutations or ALK rearrangements, and PD-L1 expression levels less than 50% or unknown; and 4) pembrolizumab/carboplatin/paclitaxel (or albumin-bound paclitaxel) for patients with metastatic squamous cell carcinoma NSCLC (preferred, category 1). The NCCN NSCLC Panel clarified the recommendations for pembrolizumab/chemotherapy in patients with metastatic nonsquamous NSCLC and PD-L1 expression levels of 1% to 49% for the 2019 update (Version 5); all of the regimens are preferred category 1 recommendations in this setting. Thus, the pembrolizumab/carboplatin (or cisplatin)/pemetrexed regimens are category 1 recommended options for patients with metastatic nonsquamous NSCLC regardless of PD-L1 expression levels; however, these regimens are preferred for those whose PD-L1 levels are less than 50% or unknown. In addition, the NCCN NSCLC Panel also clarified the recommendations for pembrolizumab/carboplatin/paclitaxel (or albumin-bound paclitaxel) in patients with metastatic squamous cell carcinoma NSCLC and PD-L1 expression levels of 1% to 49% for the 2019 update (Version 5); these regimens are preferred category 1 recommendations in this setting. The pembrolizumab/carboplatin/paclitaxel (or albumin-bound paclitaxel) regimens are category 1 recommended options for patients with metastatic squamous cell carcinoma NSCLC regardless of PD-L1 expression levels; however, these regimens are preferred for those whose PD-L1 levels are less than 50% or unknown.

Other recent updates for 2019 (Version 1) include: 1) new algorithms were added for sequencing systemic therapy with first-line PD-1 or PD-L1 inhibitors with or without chemotherapy in patients with metastatic NSCLC based on their PD-L1 expression levels and with negative or unknown test results for EGFR mutations or ALK rearrangements; and 2) the RT section in the algorithm was extensively revised; for example, some of the normal tissue dose constraints for conventionally fractionated RT were revised (see Table 5 in the Principles of Radiation Therapy in the NCCN Guidelines for NSCLC). Also, panel members voted to upgrade several regimens to category 1 recommendations (from category 2A) based on
recent trial data, including: 1) durvalumab as consolidation immunotherapy after concurrent chemoradiation for patients with unresectable stage III NSCLC;\textsuperscript{643} and 2) pembrolizumab/carboplatin/paclitaxel (or albumin-bound paclitaxel) for patients with metastatic squamous cell carcinoma NSCLC (preferred).\textsuperscript{285} For the 2019 update (Version 4), the NCCN NSCLC Panel added another recommendation for single-agent pembrolizumab as first-line therapy in patients with metastatic NSCLC regardless of histology, PD-L1 levels of 1% to 49% (category 2B), and negative or unknown test results for \textit{EGFR} mutations and \textit{ALK} rearrangements.\textsuperscript{282} Based on clinical trial data, the NCCN NSCLC Panel retained the category 1 preferred recommendation for single-agent pembrolizumab as first-line therapy in a similar setting but in patients with PD-L1 levels of 50% or more.\textsuperscript{104,282}
